DRAFT - GEOTECHNICAL DESIGN MEMORANDUM | November 19, 2021

76K02 - PS&E Package for B&O Bridge

Recommendations for Foundation Rehabilitation (Prefinal Submittal)

WJE PROJECT NO. 2014.6410.U

TO
Phil Freimuth
Senior Squad Leader
IDOT District 8

FROM
Stephen Garrett, PE - Wiss, Janney, Elstner Associates, Inc. (WJE)
Richard Walther, PE, SE - WJE
Peter Stauffer, PE (Geotechnical Engineer) – WJE
Matthew LeBlanc, PhD, PE (Geotechnical Engineer) - WJE
Chris Linneman, PE, SE - EFK Moen, LLC (EFK)
Alex Benz, PE, SE - EFK

This memorandum summarizes our recommendations related to the rehabilitation of Structure No. 082-0017 ("B&O Bridge"), specifically the rehabilitation of the above-grade foundation elements (pier caps, pier columns, and crash walls). The work is related to the development of the PS&E package for rehabilitation of this structure and is in accordance with the recommendations noted in our approved Bridge Condition Report (BCR) and Plan Development Outline. A Structure Geotechnical Report (SGR) was outside the scope of this PS&E effort.

Introduction

WJE performed a condition survey and associated analysis of the structure in 2020. "Serious" conditions consisting of multiple fractured column ties, as well as widespread corrosion related deterioration were present in the reinforced concrete foundation elements (piers and pier caps) supporting the steel superstructure. Recommendations for partial- and full-replacement were proposed and approved as part of the BCR process. Any replacement work will require temporary shoring to support the deck and steel structure to remain. Shoring systems will be supported through either shallow or deep foundations, such as piles, depending on the soil conditions.

Also during the BCR analysis, potentially liquefiable soils were identified at the structure site. The available soil investigation records from original construction and from the 1996 survey did not fully characterize the soil conditions to the extent necessary for a full liquefaction analysis. Therefore, to better characterize the risk for liquefaction, as well as to obtain the necessary soil bearing capacity information for shoring design, additional soil borings were recommended.

The following summarizes the structure, available information, rehabilitation design recommendations for substructure elements, and findings from the 2021 soils investigation.

Description of Structure

Structure No. 082-0017 was constructed in 1959. A major rehabilitation was carried out in 1988 that included replacement of the entire deck and the parapets. Seismic retrofits to elements of both the superstructure and the substructure were installed in 1998. In 2017, a limited repair scope was completed

to re-seal the expansion joints as well as perform partial depth repairs of the bridge deck and approach pavements.

The substructure consists of reinforced concrete abutments and piers. The West Abutment and Piers 1 through 9 are skewed at varying degrees. Piers 1 through 7 are oriented at a 41 degree skew while Piers 8 and 9 are oriented at a 17 degree skew to accommodate the horizontal clearances required by the five railroad tracks in operation under the structure at Spans 5, 7, 8, and 9.

The piers consist of either five or six reinforced concrete columns at each of two aligned piers that support each direction of roadway deck. A concrete pier cap with concrete bearing pads supports the individual girders. The concrete pier cap is stepped at some locations, and the pier cap at Pier 6 changes elevation to accommodate the transition from rolled to built-up superstructure girders. Per the construction drawings, the piers and abutments are founded on concrete piles. Piers 4 through 9 have crash walls which vary in height by pier location and six rectangular columns while the remaining piers are constructed of five cylindrical columns and without a crash wall at their base. The rectangular columns are 3 foot by 3 foot 3 inches at Piers 4 through 9. Piers 1 through 3 and Piers 10 through 18 are comprised of five circular columns that are 3 foot in diameter. Substructure reinforcement consists of uncoated rebar with 2 inches of clear cover.

Foundation Rehabilitation

The deteriorated substructure elements were selected for either partial- and full-replacement (pier reconstruction). Full replacement includes removal of the pier caps and all pier columns, down to the footing/pile cap. Partial replacement includes replacement of the pier caps and only the outer pier columns, down to the footing/pile cap. No below grade work was planned, and the existing footings and deep piles are to remain in place. The concrete crash walls at Pier Nos. 6, 7, 8, and 9 are larger elements relative to the columns, and local repairs were deemed a more cost-effective rehabilitation alternative than full replacement; thus, the replacement at these locations terminates at the top of the crash wall with no additional below grade excavations or removals.

As outlined below, the replacement design was such that the loading on the existing deep foundations would be relatively unchanged and thus, load testing or other investigation of the deep foundations is not required.

Substructure Analysis - Structural

For the substructure evaluation, an Abbreviated Analysis was performed. The Abbreviated Analysis consisted of verifying several aspects of the existing structure and the planned modifications (e.g., seat width extension as noted in the Abbreviated Seismic Analysis). The analysis also included determination of load conditions at the foundations to remain to confirm that the proposed service dead load is not greater than 115% of the original design service dead load.

The superstructure bearing conditions will not be changed; however, the bearings and steel bolsters will be replaced as part of the broader rehabilitation program. Replacing these elements necessitates a change in the height of the pier caps to accommodate the shallower profile for the new bearings. The pier cap widths will also increase to accommodate seismic requirements. MDX was used to analyze the superstructure and record each beam load at all the substructures. Using those loads and the volume of

concrete of each pier, the existing and proposed dead loads on the foundations were compared. After performing this analysis, it was determined that an Abbreviated Analysis was appropriate, and the existing foundations were suitable for reuse.

Abbreviated Seismic Analysis

An Abbreviated Seismic Evaluation was performed, based on the conditions in IDOT's "BCR Procedures & Practices Manual". To satisfy this evaluation, three required items were reviewed: substructure seat widths; bearing capacity; and liquefaction potential. At the reconstructed pier caps, the substructure seat widths will be modified to meet the current policy outlined in the IDOT Bridge Manual. Note, the abutments were retrofit in 1998 with seat extensions, and these elements were found to be adequate and can remain in-place with only local concrete repairs. No other seismic restraint or retrofit is deemed necessary at this time. Existing bearings and bolsters under all joints will be replaced with elastomeric bearings or fixed bearings that can withstand 20 percent of the total dead load and allowable capacity as stated in the Bridge Manual T.3.7.3-1 & 2.

A cursory review of the available soil data indicated a risk for soils liquefaction. In order to perform a more detailed analysis, additional soils testing was warranted. The existing soil data and findings from the 2021 investigation are summarized below.

Summary of Existing Soil Logs

Two geotechnical investigations were previously conducted at the B&O Bridge. Neither WJE nor EFK were involved in these previous investigations. The first investigation was completed as part of the original 1959 design and construction of the bridge. The second investigation was completed as part of the 1998 seismic analysis and retrofit program. The relevant findings from each of these investigations are summarized below.

Original Soil Borings - 1957 Investigation

Boring logs for this investigation are provided on a drawing titled *Borings and Soil Analysis* (drawings dated 1957, see Attachment 1). Borings completed beneath the western portion of the bridge generally showed approximately 3 to 7 feet of fill consisting of coal cinders and sand and clay. A brown and gray silty clay was found beneath the fill extending to approximately 9 to 18 feet depth, except for one location where the clay extended to approximately 30 feet depth. Blow counts indicated the clay was generally medium stiff to stiff with some soft clays in the middle portion of the bridge near Pier 10. The clay was underlain by a predominantly fine sand that was gray to brown in color. The sand ranged from loose to dense and extended to the bottom of the borings at 40 to 75 feet depth. Groundwater was encountered in three of the borings at 22 to 30 feet depth.

The ground surface at the borings completed east of Pier 10 was generally about 12 to 17 feet lower than the ground surface at the west borings. The east boring logs generally showed a gray silty clay from the ground surface to about 20 to 33 feet depth; no fill materials are indicated on these boring logs. The clay was generally soft with many blow count values of 1. The clay was generally underlain by a gray sand that was fine to coarse grained, and that was generally medium dense to dense with some loose intervals. The sand extended to the bottom of the borings at 40 to 60 feet depth. Groundwater was encountered in the majority of the borings at 3 to 19 feet depth.

Additional Soil Borings (Seismic Analysis) - 1996 Investigation

The geotechnical investigation that was conducted in 1996 for the seismic retrofit included three borings beneath the west portion of the bridge, and three beneath the east portion of the bridge (drawings dated 1997, see Attachment 2). Logs for borings completed beneath the west portion of the bridge showed zero to 17 feet of fill consisting of silty clay with cinders and rubble. A brown and gray silty clay was logged beginning at the ground surface to 17 feet depth, extending down to 7 to 23 feet depth. Blow counts indicated the clay was generally soft to stiff. The clay was underlain by a predominantly fine sand that was gray to brown in color. The sand was generally medium dense to dense and extended to the bottom of the borings at 75 to 81 feet depth. Groundwater was encountered in each of the three borings at 12 to 35 feet depth.

Logs for borings completed beneath the east portion of the bridge in 1996 showed fill described as "*ROCK AND CONSTRUCTION RUBBLE*" over gray silty clay loam to silty clay. The thickness of the fill is not indicated on the logs. The silty clay loam to silty clay extended to 32 to 38 feet depth. The clay was generally soft with several blow count values of zero reported. The clay was underlain by a fine to coarse gray sand that was generally medium dense to very dense. The sand extended to the bottom of the borings at 80 to 95 feet depth. Groundwater was encountered in two of the three borings at depths of 3.5 and 7 feet.

Need for Additional Soils Investigation

Though the previous soils investigations were comprehensive and provided sufficient information to complete the associated design tasks, a more detailed soils investigation was deemed appropriate given the planned rehabilitation program. Based on review of the available information, the subsurface conditions are variable across the site. Furthermore, based on review of the soil borings and Standard Penetration Tests (SPTs), potentially liquefiable soils are present at the bridge site. The available laboratory test results, soils classifications, and groundwater information were lacking detail to adequately characterize the risk for liquefaction. Additionally, to determine appropriate soil bearing capacities and soil profiles for the shoring design, borings at a closer spacing and with closer sampling intervals in the shallow depths were required.

Data collected through the previous investigations was combined with data obtained from the additional borings. Together this data serves as the basis for a more detailed investigation, which is summarized in the following section.

Summary of 2021 Soils Investigation

The relevant findings from this investigation are provided in the sections below. Also provided at the end of this report are several attachments related to the investigation and analyses. Attachment 3 provides a detailed report prepared by TSi outlining the findings of the soils investigation, including boring logs, and results from laboratory analysis; a plan view and boring locations were excerpted from the report and provide in the figures below. Attachment 4 provides excerpts from the PSE rehabilitation drawings. Attachment 5 provides a liquefaction analysis performed by WJE, in accordance with IDOT procedures.

Soil Profiles

The soil profiles were generally consistent with previous investigations, consisting of 5 to 10 feet of shallow fill overlying 20 to 30 feet of cohesive silts and clays, all of which is underlain by medium to very dense sands. The fill material is highly variable, consisting of a mixture of clay, cinders, and other miscellaneous debris that does not appear to be uniformly placed or compacted. The cohesive material underlying the fills has varying proportions of clay, silt, and sand, which resulted in SPT blow counts ranging from weight of hammer (WH) to 30 blows per foot (bpf). In some locations, this cohesive layer contains as much as 30 feet of WH soil. At depths below about 30 to 40 feet, relatively clean sands (4 to 6% fines) were encountered with blow counts as high as 67 bpf, but generally greater than about 17 bpf at a minimum.

Additionally, the extent of the site variability was better documented during this investigation as compared to previous investigations. Within the generalized layers described above, there were soil seams of varying thickness, consistency, and composition which were not encountered in all boreholes. Further, the location of the groundwater table fluctuated during the course of this investigation. During drilling, groundwater was encountered in 11 boreholes (at depths ranging between 5 and 20 feet) and was not encountered in the remaining three boreholes. After a 14-day delay, groundwater was encountered at depths between the ground surface and about 7 feet at select boring locations; borings within the areas requiring permit access were not re-evaluated. Due to the highly localized variability in the soil profile encountered in each borehole, either SPT/split-spoon or Shelby Tube samples were collected every 5 feet to depths of about 70 feet, after which samples were collected every 10 feet.

Liquefaction Potential

A detailed liquefaction analysis was performed in accordance with the IDOT Liquefaction Analysis design guide (Nov 2018), the IDOT Geotechnical Manual (Dec 2020), and the excel spreadsheet developed by IDOT to perform the liquefaction calculations, and the supporting documentation is provided in Attachment 5. In brief, a liquefaction analysis was performed for every location and depth where an SPT test was performed in the field. This field data was supplemented by additional laboratory tests (percent fines, Atterberg limits, and water content) to complete the analysis.

Ultimately, only two locations, a low plasticity silt (15-foot depth) at Pier 7 and a very loose sand (10-foot depth) at Pier 10, had a factory of safety less than 1.0; these were 0.994 and 0.936, respectively. Given that the structure is founded on deep foundations terminating approximately 24 to 45 feet below these layers and given that the factory of safety was not “substantially” less than 1.0, the foundation systems appear to meet IDOT’s requirements for seismic performance.

Temporary Support Systems

A bearing capacity and settlement analysis was performed by TSi as outlined in Attachment 3. The findings of their analysis indicate that a support foundation consisting of only a shallow footing would not be adequate to support the structure under live load due to both low bearing capacity and excessive settlement. Instead, a deep foundation (i.e., micro-piles or helical piles) will be required for the temporary support during pier reconstruction. A schematic design and estimated cost for these systems is provided

in the PS&E package for the structure. These systems are proprietary and will need to be designed by the specialty firm retained by the Contractor performing the work.

The following are additional considerations related to the use of deep foundations for the temporary support systems:

- The ground water levels in this region are high relative to the depths of the foundations, and thus de-watering of the excavations may be required during the work.
- Slope stability around any excavation should also be considered; sheet piling or other controls may be required.
- The very soft clays and potentially liquefiable soils at the near surface of the structure will contribute to the unbraced length of the piles and pose a risk for buckling. This detail could likely be mitigated through pile casings in these marginal layers or by implementing deeper excavations for the foundation.
- Bearing of the temporary shoring on the existing pile caps and foundation piles could be implemented; however, the Engineer will need to consider the effects of eccentric loading. In-situ load testing or other foundation assessments would likely be required to utilize the existing foundations for the shoring system.

Recommendations

WJE's recommendations are to proceed with the pier reconstruction utilizing a temporary support system founded on a deep foundation system. The system, selected by the Contractor, will need to be designed and sealed by a licensed Structural Engineer.

No foundation retrofit or further analysis of the structure is warranted based on the liquefaction analysis performed. During the next major rehabilitation of this structure (i.e., re-decking and/or superstructure replacement), a seismic analysis should be performed for the entire structure.

SHELBY TUBE SAMPLES
Minutes — Recovery (inches) / Seconds / Weight (pounds)
STATIC PENETRATION RECORD

X / Y — Number of Blows using 140 pound weight falling 30 inches. / Resulting Penetration in inches for X Blows.
DYNAMIC PENETRATION RECORD

CLASSIFICATION OF SOIL CONTAINED IN SHELBY TUBES IS BASED ON OBSERVATION OF THE SOIL AT THE ENDS OF THE TUBES.

Re: Subsurface Exploration and Geotechnical Engineering Evaluation
I-55/I-70 Bridge over Railroad Yard in St. Clair County
St. Clair County, Illinois
TSi Project No. 20211176.00

Dear Mr. Garrett:

TSi Geotechnical, Inc. (TSi) has completed the authorized Subsurface Exploration and Geotechnical Engineering Evaluation for the referenced project and is pleased to submit our findings to Wiss, Janney, Elstner Associates, Inc. (WJE). The purpose of our work was to assess subsurface conditions at specific test boring location in order to prepare geotechnical recommendations for use in the design and construction of the foundations and retaining structures for improvements of I-55/I-70 Bridge over Railroad Yard in St. Clair County, Illinois. This report presents the field and laboratory data, and includes our evaluations and recommendations relative to the geotechnical engineering aspects of the project.

We appreciate the opportunity to assist you with this project. If you have any questions, or if we may be of further service to you, please call us.

Respectfully submitted,
TSI GEOTECHNICAL, INC.

SUBSURFACE EXPLORATION AND GEOTECHNICAL ENGINEERING EVALUATION
I-55/I-70 BRIDGE OVER RAILROAD YARD IN ST. CLAIR COUNTY
ST. CLAIR COUNTY, ILLINOIS

1.0 SCOPE OF WORK

This report summarizes the results of a geotechnical study performed for use in the design and construction of the foundations for improvements of I-55/I-70 Bridge over Railroad Yard in St. Clair County, Illinois. Based on TSi's understanding of the project, the following items have been identified for inclusion in this study report:

- subsurface conditions at the bridge locations, including material types at each boring location;
- laboratory test results for soil samples;
- recommended foundation support for the bridge temporary support structures, as appropriate for the anticipated design loads and site conditions, and specific project requirements;
- design capacities for generalized soil profiles;
- estimated settlement of the foundations, based on the general character of the supporting materials and anticipated structural loads;
- a general assessment of regional seismicity and seismic site class;
- LPILE parameters for the design of laterally loaded deep foundations; and
- the influence of groundwater on the project;

2.0 SITE AND PROJECT DESCRIPTIONS

The following project understanding is based on the information received and discussions with WJE, and a site reconnaissance by an engineer from TSi. The project will consist of restoration work on the existing bridge piers on I-55/I70 bridge in St. Clair County, Illinois. The existing bridge carries a large amount of traffic on I-55/I-70. Based on the discussion with WJE, we understand that the bridge deck is planned to be uplifted and supported over a temporary support system consisting of hydraulic jacks, steel truss, and columns. We understand the lifting and temporary support tolerances are approximately one eighth to one half inch for a duration of approximately 40 days. The support structure is planned to be placed on an approximate 2 foot thick concrete footing constructed at the existing grades. However, ground improvements or deep foundations will likely be required to support these footings. The preliminary dimensions of the footings are provided as approximately 10 feet wide and 50 feet long. We understand the contact pressure of the footings may vary based on the pier loads and in the extreme case scenarios, it could range from approximately 1,000 to 2,000 pounds per square feet (psf) over the 10 foot by 50 foot footing.

We understand the existing bridge foundation elements are concrete piles extending to depths of 30 to 60 feet, based on provided information. After the bridge deck is supported by temporary shoring, some of the bridge piers will be excavated to the tops of the footings or pier caps for inspection and restoration.

The project site is generally located in the extended flood plain of the Mississippi River approximately 2 miles east of the main river channel. The general location of the project interchanges are shown on the Vicinity Map, Figures 1 in Appendix A of this report. The approximate locations of the borings drilled by TSi are indicated on the Site and Boring Location Plans, Figures 2.1, 2.2, and 2.3, in Appendix A.

3.0 FIELD EXPLORATION AND LABORATORY TESTING

3.1 FIELD EXPLORATION

Through August 11 to September 29, 2021, TSi conducted a subsurface exploration at the project site consisting of fourteen (14) test borings. The borings were designated as Borings 1N, 1S, 2N, 2S, 2.5, 3N, 3S, 3.5, 4N, 4S, 5N, 5S, 6N, and 6S. The boring locations were selected by WJE, and were staked in the field by TSi at the time of drilling. Some of the borings were offset from their planned locations due to utility or railroad conflicts. The approximate locations of the borings are shown on Figures 2.1, 2.2, and 2.3 in Appendix A. The boring locations were surveyed and the elevations and coordinates were provided to TSi by WJE and are shown on the Logs of Boring in Appendix B.

The borings were drilled with a Diedrich D-50 all-terrain drill rig or Geoprobe 7822DT all-terrain drill rig using hollow stem auger and mud rotary drilling methods. The borings were drilled to the predetermined depths ranging from 20 to 100 feet. The borings were backfilled with grout to the ground surface and topped with native soils. Split-spoon and Shelby tube samples were recovered from the borings. Split-spoon samples were recovered using a 2-inch outside-diameter, split-barrel sampler, driven by an automatic hammer, in accordance with ASTM D 1586. The split-spoon samples were placed in glass jars for later testing in the laboratory. Shelby tube samples were obtained in general accordance with ASTM D 1587. The Shelby tube samples were preserved by sealing the entire sample in the tube. The sampling sequences for each boring are summarized on the Logs of Boring in Appendix B.

The results of the geotechnical field tests and measurements were recorded on field logs and appropriate data sheets. Those data sheets and logs contain information concerning the exploration methods, samples attempted and recovered, indications of the presence of various subsurface materials, and the observation of groundwater. The field logs and data sheets contain the field engineer's interpretations of the conditions between samples, based on the performance of the exploration equipment and the cuttings brought to the surface by the drilling tools.

3.2 LABORATORY TESTING

A laboratory testing program was conducted by TSi to determine selected engineering properties of the obtained soil samples. The following laboratory tests were performed on the samples recovered from the borings in general accordance with the appropriate ASTM standards:

- visual descriptions by color and texture of each sample;
- hand penetrometer measurements on cohesive samples;
- natural moisture content of each cohesive sample;
- unit weights of selected samples;
- minus #200 washed sieves of selected samples;
- sieve particle size analysis of selected samples;
- hydrometer test;
- consolidation tests of selected Shelby tube samples;
- Atterberg limit tests on selected cohesive samples; and
- Unconsolidated undrained triaxial compressive strength of selected soil samples.

Data and observations from laboratory tests were recorded on laboratory data sheets during the course of the testing program. The results of the tests are summarized on the Logs of Boring in Appendix B and on the Laboratory Test Reports in Appendix C. The boring logs are an interpretation of the subsurface conditions based on the field and laboratory data. Only data pertinent to the objectives of this report have been included on the logs; therefore, these logs should not be used for other purposes.

4.0 SUBSURFACE CONDITIONS

Details of the subsurface conditions encountered at the boring locations are shown on the Logs of Boring. The general subsurface conditions encountered and their pertinent engineering characteristics are described in the following paragraphs. Conditions represented by the borings should be considered applicable only at the location drilled on the dates shown; the reported conditions may be different at other locations or at other times.

4.1 GENERAL GEOLOGY

The general area of the project site is underlain by Ste. Genevieve Limestone of Mississippian system, of the Chesterian Series at an estimated depth between 100 and 200 feet. This limestone formation may contain layers of dolomite, limestone breccia, shale and chert. The upper few feet of bedrock is typically weathered and highly weathered in some areas. The limestone is susceptible to solution activity, resulting in sinkholes that may be filled with more recent sediments, an irregular bedrock surface, and widened joints with variable degrees of weathering. Some calcareous sandstone layers and local cherts can be found. The Ste. Genevieve Limestone has been heavily eroded in this area during the Pennsylvanian by alluvial action. Expected thicknesses vary from 0 to 150 feet.

Based on the Illinois Geological Survey the native surface soil deposits consist of alluvial sediments from the Cahokia Formation extending to a depth of over 100 feet. The Cahokia Formation typically consist of bedded silts, clays, loams, and sand and gravel deposited in the floodplains and channels of modern rivers and streams. The project site is situated in the apparent oxbow remnant of the Mississippi River where sediments slowly filled the river meander until it was completely cut off from the main channel. Remnant lakes, ponds, creeks, and canals are present throughout the general area.

4.2 GENERALIZED SUBSURFACE PROFILE

The generalized subsurface profile of the borings consists of highly variable fills overlying cohesive soils consisting of silts and clays, all of which is underlain by native sands.

The surficial fill soils consist of approximately 5 to 10 feet of highly variable material with consistency ranging from very soft to hard. Fill materials consist of cinders, clay, silty loams, loams, sandy loams, sandy clays, and sands (as per IDOT IDH soil classification system) with variable amounts of secondary clays, silts, sands, gravel, brick, glass, and limestone fragments. SPT (Standard Penetration Test) N-values ranged from WH (weight of hammer) to >50 bpf (blows per foot). Moisture contents in the fill range from about 4 to 56%. Dry densities in the fill ranged from about 87 to 106 pcf (pounds per cubic foot). Atterberg limits in the fill range from 55 to 114 liquid limits and 36 to 86 plastic indices. Undrained shear strengths in the fill range from about 0.38 to 0.66 tsf (tons per square foot). Percent fines passing a #200 sieve range from about 15 to 98%.

The upper cohesive materials which underlie the fills appear to be relatively recently deposited sediments from the Mississippi River, previous oxbow remnants, creeks, or canals. These cohesive native soils varied from depths of about 5 to 40 feet and consist of clays, silts, silty clays, clay loams, silty clay loams, loams, sandy clays, and sandy clay loams with consistencies ranging from very soft to stiff. N-values range from WH to 30 bpf. N-values were generally lower on the northern half of the project area. Moisture contents in the cohesive soils ranged from about 22 to 75%. Dry densities in the cohesive soils range from about 75 to 101 pcf. Atterberg limits in the cohesive soils range from 22 to 99 liquid limits and 3 to 86 plastic indices. Undrained shear strengths in the tested cohesive soils range from about 0.45 to 0.71 tsf. Percent fines passing a #200 sieve range from about 50 to 99% in selected samples.

Some of the very soft clays present in the surface fill materials and upper cohesive sediment soils could not be recovered in Shelby tube or SPT samples to produce reliable testing specimens due to the very soft and wet characteristics. These include soils with weight of hammer SPT values and high moisture contents, some near their liquid limit values. These very soft soils are likely softer and weaker than the tested lab specimens.

Below depths of about 30 to 40 feet, native sands were encountered of generally medium dense to dense consistency. SPT N-values ranged from WH to 67 bpf, generally being above 8 bpf. Moisture contents in sands ranged from about 6 to 32%. Percentage of fines ranged from about 4 to 6% in selected samples.

4.3 GROUNDWATER

Groundwater was encountered during drilling at depths of 5 to 20 feet, except in Borings B-1N, B-4N, and B-6N. Selected borings were observed for groundwater after a 14 day delay. Groundwater was encountered on delayed readings between the ground surface and 6.8 feet. The depths of groundwater for each boring are presented on Table 1 below. The presence or absence of groundwater at a particular location does not necessarily mean that groundwater will be present or absent at that location at other times. Groundwater levels may vary significantly over time due to the effect of seasonal variations in precipitation or other factors not evident at the time of exploration.

TABLE 1.
GROUNDWATER DEPTHS AND ELEVATIONS

		During Drilling		14-Day Delay	
Boring	**Ground Elevation (ft.)**	**Depth (ft.)**	**Elevation (ft.)**	**Depth (ft.)**	**Elevation (ft.)**
B-1N	416.0	NE	NE	0.0	416.0

5.0 DESIGN RECOMMENDATIONS

5.1 EXISTING FILL MATERIALS

Existing fill materials were encountered at the boring locations extending to depths ranging from approximately 5 to 10 feet below the existing ground surface. The existing fill materials generally consisted on clay or cinders, a burnt coal byproduct, with varying percentages of miscellaneous debris such as brick, asphalt, glass, and concrete fragments. It does not appear that all of the fill was placed and compacted in a controlled manner. As a result, the engineering properties of the fill cannot be predicted with certainty, and there is a risk for excessive total or differential settlement or other performance problems if any structures are supported on the existing fill. Fill materials with greater variability and thickness could also be present between or away from the boring locations.

Several options are available for mitigating the risks associated with the old fill material, the most common of which are described below. It will ultimately be the decision of the owner to decide which course of action to take, based on a comparison of risks that result from the presence of the fill with the costs associated with reducing or eliminating the risks.

Complete Removal and Replacement – The risks associated with building upon the existing fill may not be acceptable to owner and designers. In order to eliminate the risk to the proposed shoring project, the existing fill could be removed entirely from the planned development areas and replaced with compacted, suitable fill. The excavation bases should be widened by a minimum of one half foot in each direction larger than the proposed footing for every foot of excavation below surface grade. Old fill that proves to be relatively uniform in composition and free of deleterious materials may be reused as new fill. See Section 6.4, *Fill and Backfill Materials*.

Additional Options – TSi understands that complete fill removal and replacement may not be practical or economically feasible due to the depths of fill and surrounding structures, utilities, and railroads to remain. Other options for mitigating the presence of the old fill include deep foundations and ground improvement. Deep foundations could include drilled shafts or driven piles.

Ground improvements, such as rammed aggregate piers, GeoPiers or vibro-replacement/vibro-compaction (stone columns), are possibilities to improve the ground for temporary shoring for the lighter loaded structures for the project. These technologies could be effective at mitigating the uncertainties associated with the existing fill and reduce the potential for differential settlements. The performance of the improvement columns is dependent on the proprietary system used for installation. The design of these systems is normally accomplished by the specialty subcontractor awarded the installation, based on a performance specification for

allowable bearing capacity and settlement of the foundations. However, as previously mentioned the vibrations induced by these ground improvement methods could cause settlement and damage to the existing foundations.

5.2 Bearing Capacity

Very soft clayey soils were encountered below the fill materials at this site. In addition, existing fill materials at some areas do not appear to have a proper compaction based on their relatively low Standard Penetration Resistance (N-value) and high moisture contents near the soils liquid limits. Based on the encountered soil materials, the most probable mode of failure for a footing at this site is expected to be the local or punching shear failures. In these modes of failure, the shear strength mostly generates from a limited wedge of failure and as a result a lower bearing capacity is associated with these types of failure. A conventional approach to address this issue is to reduce the shear strength parameters of the soil to two-third of their estimated values. The bearing capacity equation used in our evaluation are provided below:

$q_{\text{net,allowable}} = (\pi+2)\times 0.67\times \text{Cu/SF}$

In the above equation "SF" is the Safety Factor. The safety factor for bearing capacity is typically 3 or more for permanent structures. For temporary structures the safety factor could be as low as 1.5 to 2.0 due to the short term duration of this project; however, excessive settlements would likely result. The "Cu" in the equation is the undrained cohesion or shear strength of the underlying clays.

The fill materials encountered to depths of 5 to 10 feet in the borings exhibited tested shear strengths as low as about 640 psf. The native cohesive soils encountered at depths of 5 to 40 feet exhibited tested shear strengths as low as about 900 psf of the tested samples. However, as previously indicated, very soft fill and native soils were encountered with in-situ SPT N-values of weight of hammer which indicate very soft soils. Laboratory tests also verify very high moisture contents near their liquid limit values in some of these very soft soils. Penetration tests of some of these samples indicate shear strengths as low as 250 psf. The drilling and laboratory tests results are consistent with anticipated sediments of the Cahokia Formation and indicate layers of these very soft soils are present in many areas of the project site where foundations are planned.

The lower range Cu of some of the soils within the bearing strata below the foundation bases are estimated to be about 250 psf. As a result, the net allowable bearing capacity of the underlying soft clays is about 435 to 580 psf using safety factors of 1.5 and 2.0, respectively. Since, in the clayey soils, the embedment depth of foundation does not have an influence on the bearing capacity, the above estimated capacity would be valid for both 5 and 10 feet removal and replacement of the materials with crushed limestone. The transferred stresses to the bottom of the

crushed limestone layer should be compared against the provided net allowable bearing capacity. The transferred load to the underlying layers could be estimated by the 2 to 1 method. In this approach the contact pressure at deeper depths is calculated over an enlarged area which is expanded by a 2 Vertical:1 Horizontal (2H:1V) line from the perimeter of the strip footings. It should be noted that the difference in unit weight of crushed limestone and the underlying clays (about 20 pcf) should also be added to the calculated values. Therefore, the estimated contact pressure at the bottom of the crushed limestone layer is estimated to be approximately 1,300 and 1,000 psf for 5 and 10 feet thick crushed limestone pads, respectively.

As it is evident, these estimated contact pressure magnitudes are much greater than the net allowable bearing capacity provided in the previous paragraphs and as a result the proposed footings at this site are subject to failure under the provided loading conditions. Local bearing failure may not occur in all portions of planned footings, but the potential for failure in some portions are high. This also applies to the lighter structures with an approximate surface contact pressure of 1,000 psf if these very soft clays are present in the upper cohesive layer from depths of 10 to 20 feet. However, if these soft soils are not present below any part of the 10 foot by 50 foot footing as encountered in some of the borings, the local bearing capacities may not be exceeding under the design loadings, but excessive total or differential settlement could result. The following section evaluates these potential total and differential settlements.

5.3 Settlement Analysis

A variable range of conditions including fill to depths of 5 to 10 feet with very soft to stiff consistencies underlain by very soft to medium stiff clays, silty clays, loams to depths of 15 to 20 feet. Present in some of the borings are a very soft clay with moisture contents from about 40 to 90%. Below depths of about 30 to 40 feet sands were encountered in all the borings to the termination depths of 60 to 100 feet. Due to the large range of variability in the soil profiles, a conservative soil profile was established for settlement analysis. The following analysis represents the potential maximum settlements under the highest loadings.

TSi performed settlement analysis using UniSettle 4.0 software developed by UniSoft Geotechnical Solutions for this site. The soil layers and properties utilized in our analyses were generalized based on the field and laboratory results of the borings drilled at this site. A discussion of the field and laboratory tested strength values are presented in the previous section, 5.2 Bearing Capacity. Other soil parameters used for the settlement analysis were derived from the consolidation tests, moisture contents, and Atterberg limit index properties. A composite soil profile of conservative soil conditions are presented below in Table 2.

TABLE 2.
SETTLEMENT ANALYSIS LAYERS

Material	General Depth Ranges Encountered in Borings (ft.)	Depth Ranges for Settlement Analysis (ft.)
Fill	5 to 10	0 to 10
Loam and Silty Clay	5 to 20	10 to 15
Clay	15 to 40	15 to 40
Sand	30 to 100	40 to 100

The estimated immediate and consolidation settlements and total and differential settlements for a footing 10 feet wide, 50 feet long with a contact stress of 2,000 psf are provided in the below Table 3. Settlements of foundations with a lower contact stress of 1,000 psf are estimated to be over half of the settlements in Table 3. Immediate settlements of properly compacted crushed stone should be negligible in comparison to the settlement of the existing fills and underlying native soils.

TABLE 3.
SETTLEMENT ANALYSIS RESULTS

Improvements	Potential Immediate Settlement (in.)	Potential Consolidation Settlement (in.)	Consolidation Settlement within 40 Days (20 to 40%) (in.)	Total Amount of Settlement within 40 Days (in.)	Differential Amount of Settlement within 40 Days (in.)
None (footing support over the subgrade)	3.5 to 6.5	12 to 15	2.5 to 6	6 to 13	7 to 9
5-ft thick crushed limestone pad	3 to 6	9 to 11	2 to 4.5	5 to 10.5	5.5 to 7
10-ft thick crushed limestone pad	2.5 to 5.5	7.5 to 9.5	1.5 to 4	4 to 9	5 to 5.5

If the local bearing capacities are not exceeded that produce a local shear failure and complete foundation failure the above ranges of total and differential settlement could result. The total settlement is measured at the center of the 10 ft. and 50 ft. pad and the differential compares this center with the ends of the pad. Some of these total and differential settlements could be actively managed with active jacking systems that could require constant adjustment over the construction period. However, the differential settlement could cause the pad to crack and potentially fail unless it is reinforced and designed to deflect. Potential continued settlement could also make it difficult to actively support the bridge decks with a jacking system within the tolerance of about 1/8 inch to 1/2 inch.

5.4 Foundation Recommendations

Based on our engineering evaluations, the proposed foundations could undergo a catastrophic bearing capacity failure and the amount of differential settlement may not be able to be tolerated by a 2 foot thick concrete footing at the ground surface or underlain by 5 to 10 feet of newly compacted crushed limestone backfill. Therefore, we do not recommend the proposed structure at this site be supported over a shallow foundation system. TSi recommends a deep foundation system, such as micropiles or helical piles, be utilized for this project bearing in sands underlying the weak clays at depths below about 30 to 40 feet.

Since, very soft clay materials were encountered in most of our borings, we recommend a rigid foundation element be considered, since the very soft materials encountered in our borings do not provide a sufficient lateral resistance and may subject a slender deep foundation element to buckling or significant axial deflections.

Other deep foundation systems such as drilled shaft or driven piles could be used for foundation support; however, limited access under the bridges and very close proximity to the railroad tracks greatly limit or preclude the constructability of these foundation types. Other ground improvements such as rammed aggregate piers may be able to provide sufficient foundation support, but the vibrations required to install these elements could cause subsidence and potential damage to the existing pile support system.

5.5 Micropile / Helical Pile Foundations

As previously discussed, micropiles and helical piles could be considered to support the temporary shoring for the bridge decks, considering the confined work space and close proximity to railroad tracks. The installation of micropiles and helical piles is proprietary, where a specialty contractor designs and installs the foundations and is the engineer-of-record for the foundation system. The specialty contractors should be contacted for the design details regarding micropiles and helical piles. We suggest the deep foundation systems be designed to a performance criteria applicable to the project requirements. We anticipate a grid of deep foundation elements would be installed into the existing ground and structural cast into the planned concrete foundation pad.

Assuming that the micropiles are pressure-grouted and based on the borings, we recommend a preliminary allowable axial side resistance (grout-to-ground bond resistance) average value of 50 to 100 psf for the upper cohesive soils and 600 to 800 psf for the underlying sands. Uplift resistance for individual piles may be taken as two thirds of the allowable axial side resistance. These values include a Factor of Safety of 2.5. The success of the micropile installation is dependent on the experience and skill of the contractor. As such, and because of the limited subsurface at the site, the specialty contractor should determine the appropriate skin friction value, spacing, diameter, configuration and length of pile to achieve the required capacity at each shoring location.

Helical piles are used for foundation support, they should be turned into the ground until they achieve the required design capacity for each element generally associated to the required installation torque. The high capacity elements required for this project will likely be pipe piles with multiple helices turned into the sands below depths of 30 to 40 feet and then possibly grouted for additional lateral load capacity.

The allowable group uplift capacity should be compared to the allowable uplift capacity of a single pile multiplied by the number of piles in the group and the design should be based on the lesser group capacity where applicable.

One potential issue with single-element micropiles or helical pile is that they can have limited lateral capacity, due to the threads in micropile or helical pile extension sections. If that is the case, then battered micropiles or helical piles can be utilized to accommodate the lateral capacity. A single section micropile or helical pile without threads between the sections could also provide lateral capacity. TSi recommends that at least two micropiles be performance-tested to verify the grout-to-ground bond strength. Only the design bond length of the bar should be grouted for testing of the micropile. At least two helical piles should also be tested to confirm the design capacities.

We recommend that the micropile testing and installation be performed in accordance with the Federal Highway Administration Micropile Design and Construction Manual, FHWA-SA-97-070. The piles should be installed to the required embedment depth using sufficient equipment to penetrate through the upper variable fill and cohesive soils. Spacing of the piles should be at least 3 diameters center to center to avoid stress overlap and to avoid impacting the adjacent pile. The 28-day compressive strength of the grout should be at least 4,000 psi. Actual grout volumes in excess of the predicted volumes should be anticipated due to the highly variable fill and very soft clays noted on the boring logs, as well as the potential for voids within the fill.

5.6 Lateral Load

The lateral load capacity of the deep foundations will vary based on their width, depth, and variable material penetrated. For a lateral load analysis, we recommend using the LPILE program from

Ensoft, Inc. For the LPILE analyses, recommended geotechnical parameters for the soil are provided in the following table:

TABLE 4
LPILE PARAMETERS

Depth (feet)	LPILE Material Type	Effective Unit Weight* γ', pcf	Undrained Cohesion psf	E_{50} Value	Static p-y Modulus, k (pci)
0 to 10	Soft Clay (Matlock)	120	250	0.020	30
10 to 15	Stiff Clay w/o free water	52.6	750	0.01	100
15 to 40	Soft Clay (Matlock)	57.6	250	0.020	30
60 to 100	Sand (Reese)	47.6	36 deg.**	NA	97

* Assumed groundwater at 10 ft., ** Internal friction angle.
pcf = pounds per cubic foot, psf = pounds per square foot, pci = pounds per cubic inch

5.7 REGIONAL SEISMICITY

Although several significant areas of seismic activity exist in the central United States, the St. Louis area is most directly affected by the New Madrid and the Wabash Valley Seismic Zones. The New Madrid zone has its northern limits located in the bootheel area of southeast Missouri and the southern tip of Illinois. The zone is essentially defined by the Mississippi Embayment, an area where deep sedimentary deposits have accumulated above basement rock. The zone continues to be active, with small tremors (micro-earthquakes) occurring regularly. The seismic history of the zone is dominated by a series of strong earthquakes that occurred from 1811 through 1812. Studies indicate the major shocks from these events resulted in an energy release equivalent to a body wave Magnitude 7.5 event. The Wabash Valley zone, located in the southern and central portions of eastern Illinois and western Indiana, is also considered to be capable of generating major seismic events.

Based on the general soil characteristics as determined by field and laboratory tests and the estimated depth to bedrock, the project area is designated as Site Class E, in accordance with the ASCE 7.0 if the soils are not subject to liquefaction. N-values suggest that some of the soils do not have adequate density and cohesion to resist liquefaction in consideration of the distance to known seismic sources. Thus, some of the site soils could be considered to be susceptible to liquefaction, or to substantial settlement or loss in strength when subject to the design earthquake loading. We understand that WJE is conducting a liquefaction analysis of the site soils in

accordance with IDOT design procedures. This analysis can be used to determine the potential liquefaction effects and design considerations.

6.0 Site Preparation and Excavation Considerations

Earthwork tasks should be performed in accordance with the Illinois IDOT Specifications for Construction.

6.1 Subgrade Preparation

Construction areas should be stripped of existing pavement, organic soil, and any deleterious materials prior to site excavation and grading. Care should be taken during stripping to prevent excessive disturbance of the underlying soil. After the removal of these materials, and where further excavation is not required, the exposed subgrade should be proofrolled. Proofrolling is accomplished by passing over the subgrade with proper equipment such as a fully loaded tandem-axle dump truck or scraper and observing the subgrade for areas of excessively soft, wet, disturbed, or otherwise unsuitable soils. Any unacceptable materials encountered should be excavated and either recompacted or replaced with new structural fill. However, soft soils could be deeper than the planned excavations. A geotextile grid sized for the backfill and support requirements could be used to bridge soft soils to allow proper compaction of the backfill materials.

Some excavations to depths of 5 to 10 feet could encounter groundwater that would require dewatering prior to placement of materials. Depending on the local weather, precipitation and groundwater levels, removal of the water may be accomplished using sump and pump arrangements. The use of well points could be required to dewater the excavations if high groundwater flows are encountered during construction. Use of a thin mud mat consisting of 1 to 2 inches of concrete may be placed in the base of the excavations to provide a protective layer prior to placing fill and to reduce disturbance of the subgrades.

Prior to placing fill in any area not previously stabilized by a mud mat or geogrid, the subgrade should be scarified to a depth of about 6 inches, the moisture content adjusted to near its optimum moisture content, and the subgrade recompacted in accordance with recommendations made in subsequent sections of this report. The recommended proofrolling and/or scarification and recompaction may be waived if, in the opinion of TSi, this procedure would be detrimental or unnecessary. Following the satisfactory preparation of the subgrade, controlled fill material may be placed.

6.2 Temporary Excavation Support

Trenching and bracing for any temporary excavations should be performed in accordance with the Occupational Safety and Health Administration (OSHA) regulations, and other applicable regulatory agencies. In accordance with the OSHA excavation regulations, the soils that will be encountered in the excavations are classified as Type C, which requires a side slope for the

trench excavation no steeper than 1.5 horizontal to 1.0 vertical (1.5H:1V). However, worker safety and classification of the excavated soil is the responsibility of the contractor.

Excavation support such as timber sheeting and bracing, or sheet piling, may be utilized in lieu of sloping back the sides of the excavations. Also, according to OSHA requirements, any excavation extending to a depth of more than 20 feet must be designed by a registered professional engineer.

Where the excavations lie within the zone of influence of utilities, railroads, or other structures, the integrity of those elements should be maintained by a properly designed earth retention system, underpinning, or other suitable means. The existing structures located adjacent to the development area must not be undermined or otherwise compromised by the excavation activities.

6.3 Subgrade Protection

Construction areas should be properly drained in order to reduce or prevent surface runoff from collecting on the exposed subgrade. Any ponded water on the exposed subgrade should be removed immediately.

To prevent unnecessary disturbance of the subgrade soils, heavy construction vehicles should be restricted from traveling through the finished subgrade. Temporary subgrade support such a surface layer of crushed stone up to 3 inches in maximum particle size could be required to provide access to heavy construction equipment during deep foundation installations. If areas of disturbed subgrade develop, they should be properly repaired in accordance with the recommendations in this report.

6.4 Fill and Backfill Materials

All fill materials and fill placement methods at the replacement bridge sites must be completed according to Illinois Department of Transportation standards and specifications. Some of the soils encountered at the borings would be acceptable fill materials according to these specifications. Soil with decayable material such as cinders, wood, trash, metal, or vegetation is not acceptable.

Some of the fill material may require the addition of moisture prior to compaction. This should be performed in a controlled manner using a tank truck with a spray bar, and the moistened soil should be thoroughly blended with a disk or pulverizer to produce a uniform moisture content. Repeated passages of the equipment may be required to achieve a uniform moisture content. If fill is placed during the winter season, fill materials should be carefully observed to see that no ice or frozen soils are placed as fill or remain in the base materials upon which fill is placed.

Some of the fill material may require moisture reduction prior to compaction. During warm weather, moisture reduction can generally be accomplished by disking, or otherwise aerating the soil. When air-drying is not possible, a moisture-reducing chemical additive, such as lime or Class C fly ash, may be used as a drying agent. These additions should be thoroughly mixed prior to compaction.

6.5 Fill and Backfill Placement

Cohesive fill should be compacted to a dry density of at least 95% of the standard Proctor maximum dry density (ASTM D 698) of the soil. Cohesive fill placed in areas where fill depths are greater than 5 feet should be compacted to a dry density of at least 98% of the standard Proctor maximum dry density. Granular material, such as crushed limestone, placed for structure or pavement support, should be compacted to at least 100% of the standard Proctor maximum dry density. The moisture content of clay or granular fill at the time of compaction should be up to 3% above optimum moisture content as determined by the standard Proctor compaction test. Fill should be placed in loose lifts not in excess of 8 inches thick, and compacted to the aforementioned criterion. However, it may be necessary to place fill in thinner lifts to achieve the recommended compaction when using small hand-operated equipment. Heavy compaction equipment should be avoided and light equipment should be used for compacting the backfill materials close to the bridge structures.

7.0 CONSTRUCTION OBSERVATION AND TESTING

It is recommended that TSi be retained during construction to perform testing and observation services for the following items:

- proofrolling, recompaction, and preparation of the soil subgrade that will support new fill;
- evaluation of the suitability of fill and backfill materials;
- placement and compaction of fill and backfill;
- observation and documentation of the installation of ground improvement or deep foundations; and
- quality assurance testing for concrete materials.

These quality assurance services should help to verify the design assumptions and maintain construction procedures in accordance with the project plans, specifications, and good engineering practice.

8.0 REPORT LIMITATIONS

This report has been prepared for the exclusive use of **WISS, JANNEY, ELSTNER ASSOCIATES, INC.** for the specific application to the subject project. The recommendations contained in this report have been made in accordance with generally accepted soil and foundation engineering practices; no other warranties are implied or expressed.

The analyses and recommendations submitted in this report are based in part upon the data obtained from the test borings. The nature and extent of variations between the borings may not become evident until construction. If variations then appear evident, it may be necessary to re-evaluate the recommendations of this report.

We emphasize that this report was prepared for design purposes only and may not be sufficient to prepare an accurate construction bid. Contractors reviewing this report should acknowledge that the information and recommendations contained herein are for design purposes.

If conditions at the site have changed due to natural causes or construction operations, this report should be reviewed by TSi to determine the applicability of the analyses and recommendations considering the changed conditions. The report should also be reviewed by TSi if changes occur in the structure locations, sizes, and types, or in the planned loads, elevations, or project concepts.

TSi requests the opportunity to review the final plans and specifications for the project prior to construction to verify that the recommendations in this report are properly interpreted and incorporated in the design and construction documents. If TSi is not accorded the opportunity to make this recommended review, we can assume no responsibility for the misinterpretation of our recommendations.

		-25			
		-30			
		-35			
		-40			

The U.C.S. Qu column represents the Unconfined Compressive Strength using either the IDOT Rimac Test Procedure or AASHTO 208.
The Qu failure mode is indicated by B for Bulge or S for Shear. P is shown when sample disturbance only allows Penetrometer testing.
The Standard Penetration Test (SPT) N value is the sum of the second and third Blows /6 in. values in each sample using AASHTO T 206.

		-35			
		-40			

The U.C.S. Qu column represents the Unconfined Compressive Strength using either the IDOT Rimac Test Procedure or AASHTO 208.
The Qu failure mode is indicated by B for Bulge or S for Shear. P is shown when sample disturbance only allows Penetrometer testing.
The Standard Penetration Test (SPT) N value is the sum of the second and third Blows /6 in. values in each sample using AASHTO T 206.

The U.C.S. Qu column represents the Unconfined Compressive Strength using either the IDOT Rimac Test Procedure or AASHTO 208.
The Qu failure mode is indicated by B for Bulge or S for Shear. P is shown when sample disturbance only allows Penetrometer testing.
The Standard Penetration Test (SPT) N value is the sum of the second and third Blows /6 in. values in each sample using AASHTO T 206.

The Standard Penetration Test (SPT) N value is the sum of the second and third Blows /6 in. values in each sample using AASHTO T 206.

GENERAL NOTES

The number of borings is based on: topographic and geologic factors; the magnitude of structure loading; the size, shape, and value of the structure; consequences of failure; and other factors. The type and sequence of sampling are selected to reduce the possibility of undiscovered anomalies and maintain drilling efficiency. Attempts are made to detect and/or identify occurrences during drilling and sampling such as the presence of water, boulders, gas, zones of lost circulation, relative ease or resistance to drilling progress, unusual sample recovery, variation in resistance to driving split-spoon samplers, unusual odors, etc. However, lack of notation regarding these occurrences does not preclude their presence.

Although attempts are made to obtain stabilized groundwater levels, the levels shown on the Logs of Boring may not have stabilized, particularly in more impermeable cohesive soils. Consequently, the indicated groundwater levels may not represent present or future levels. Groundwater levels may vary significantly over time due to the effects of precipitation, infiltration, or other factors not evident at the time indicated.

Unless otherwise noted, soil classifications indicated on the Logs of Boring are based on visual observations and are not the result of classification tests. Although visual classifications are performed by experienced technicians or engineers, classifications so made may not be conclusive.

Generally, variations in texture less than one foot in thickness are described as layers within a stratum, while thicker zones are logged as individual strata. However, minor anomalies and changes of questionable lateral extent may appear only in the verbal description. The lines indicating changes in strata on the Logs of Boring are approximate boundaries only, as the actual material change may be between samples or may be a gradual transition.

Samples chosen for laboratory testing are selected in such a manner as to measure selected physical characteristics of each material encountered. However, as samples are recovered only intermittently and not all samples undergo a complete series of tests, the results of such tests may not conclusively represent the characteristics of all subsurface materials present.

NOTATION USED ON BORING LOGS

APPROXIMATE PROPORTIONS

TRACE	<15%
WITH	15-30%
MODIFIER	>30%

Clay or clayey may be used as major material or modifier, regardless of relative proportions, if the clay content is sufficient to dominate the soil properties.

PARTICLE SIZE

BOULDERS		>12 Inches
COBBLES		12 Inches – 3 Inches
GRAVEL		
	Coarse	3 Inches – ¾ Inch
	Fine	¾ Inch – No. 4 Sieve (4.750 mm)
SAND		
	Coarse	No. 4 – No. 10 Sieve (2.000 mm)
	Medium	No. 10 – No. 40 Sieve (0.420 mm)
	Fine	No. 40 – No. 200 Sieve (0.074 mm)
SILT		No. 200 Sieve - 0.002 mm
CLAY		< 0.002 mm

PENETRATION – BLOWS

Number of impacts of a 140-pound hammer falling a distance of 30 inches to cause a standard split-barrel sampler, 1 3/8 inches I.D., to penetrate a distance of 6 inches. The number of impacts for the first 6 inches of penetration is known as the seating drive. The sum of the impacts for the last 12 inches of penetration is the Standard Penetration Test Resistance or "N" value, blows per foot. For example, if blows = 6-8-9, "N" = 8+9 or 17.

OTHER NOTATIONS

Recovery % – length of recovered soil divided by length of sample attempted.

50/2"	Impacts of hammer to cause sampler to penetrate the indicated number of inches
WR	Sampler penetrated under the static loading of the weight of the drill rods
WH	Sampler penetrated under the static loading the weight of the hammer and drill rods
HSA	Hollow stem auger drilling method
FA	Flight auger drilling method
RW	Rotary wash drilling methods with drilling mud
AH	Automatic hammer used for Standard Penetration Test sample
SH	Safety hammer with rope and cathead used for Standard Penetration Test sample

GRAPHIC SYMBOLS

Depth at which groundwater was encountered during drilling

Depth at which groundwater was measured after drilling

Standard Penetration Test Sample, ASTM D1586

Excerpts from PreFinal PS&E Package

Benchmark: *BM 207: Cut "□" on top of northeast end of parapet wall on the northeast end of the I-55/70 bridge (SN 082-0017) over RR tracks. Elev. 426.204.*
BM 208: Cut "□" on top southwest side of the southwest concrete overhead signpost foundation over I-55/70, north of I-55/70, just northwest of the I-55/70 bridge over the railroad (SN 082-0017). Elev. 437.486.

Existing Structure: *S.N. 082-0017 originally built in 1959 as Section 82-5VB. The back-to-back length is 1618'-11¾" and out-to-out deck width is 116'-0". The structure is a 19 span multi-unit non-composite steel wide flage beam or built-up riveted plate girder bridge on stub abutments and multi-column spread footing piers founded on metal shell piles. Traffic to be maintained using staged construction.*

Salvage: *None*

PLAN

SCOPE OF WORK

1. Partial and full depth concrete deck repairs.
2. Repairs to the parapet and replacement of the longitudinal joint along median barriers, between structures.
3. Installation of ten (10) new preformed joint strip seals, including removal and replacement of deck and parapet concrete each side of joint.
4. Installation of asphalt wearing surface with waterproofing system.
5. Replacement of cracked superstructure elements and repairs to local cracks.
6. Steel superstructure section loss repairs.
7. Steel coating on fascia girders and at all girder ends under expansion joints as shown on plans.
8. Replacement of fixed and expansion bearings below expansion joints.
9. Seismic retrofit rehabilitation.
10. Removal and reconstruction of pier caps and all columns for Pier 3, 6, 13, & 16.
11. Removal and reconstruction of pier caps and outside columns for Pier 7 thru 10.
12. Repairs to abutments and concrete pier caps, columns, and crash walls for all piers that are not reconstructed.
13. Drainage System Repair at Pier 9.

MEMORANDUM | November 5, 2021

WO30 - Soils Investigation for B&O Bridge

Liquefaction Analysis

WJE PROJECT NO. 2014.6410.T

TO FILE

FROM Peter Stauffer, Matthew LeBlanc

This memorandum summarizes the results of WJE's liquefaction analysis related to the rehabilitation of Structure No. 082-0017 ("B&O Bridge"), specifically the rehabilitation of the above-grade foundation elements. The liquefaction analysis followed the procedures outlined in the IDOT Liquefaction Analysis design guide (Nov 2018), the IDOT Geotechnical Manual (Dec 2020), and the excel spreadsheet developed by IDOT to perform the liquefaction calculations. These references can be downloaded from the IDOT website here: https://idot.illinois.gov/doing-business/procurements/engineering-architectural-professional-services/Consultants-Resources/index.

Since portions of Illinois are considered "multi-modal" in that there are multiple earthquake sources that have a significant contribution to the overall hazard, IDOT requires liquefaction potential at the site to be checked for multiple seismic sources to determine the source that results in the highest Peak Ground Acceleration (PGA) at the site. The information needed to determine the controlling source was obtained using the USGS earthquake database (https://earthquake.usgs.gov/hazards/interactive/) and a return period of 1000 years. Note that even though the site is likely Site Class E based on the thickness of the soft clay layer underlying the site (Table 6.12.2.1.1-1; IDOT Geotechnical Manual), the lowest site class that the USGS database will allow the user to select for this site's location based on latitude/longitude is "B/C Boundary (shear wave velocity = 760 m/s)." According to the USGS database, there are five actual earthquake sources of various magnitudes and source-to-site distances that have a contribution to the total hazard greater than 5% (IDOT criteria) at the location of the B&O bridge. The PGA for each earthquake was calculated using ground motion prediction equations in the IDOT liquefaction analysis spreadsheet to determine the worst-case (highest) PGA at the site (summarized below in Table 1).

Table 1. Determination of Highest PGA at the B&O Bridge Site

Source-to-Site Distance (km)	Earthquake Moment Magnitude (M_w)	Ground Motion Prediction Equation[1]	PGA (g)
12.68	4.7	CEUS	0.148
12.68	4.9	CEUS	0.182
12.68	5.1	CEUS	0.222 (worst-case)
190	7.5	NMSZ	0.074
230	7.7	NMSZ	0.070

[1] IDOT requires Central Eastern United States (CEUS) equations for near-site sources and the New Madrid Seismic Zone (NMSZ) equations for distant sources

The IDOT liquefaction analysis spreadsheet also requires the peak horizontal acceleration coefficient at the ground surface, A_s, to compute the factor of safety (FS) against liquefaction. This coefficient is calculated by the equation $A_s = F_{pga} \times PGA$, where F_{pga} is the zero-period site amplification factor. Based on Table 3.10.3.2-1 in AASHTO LRFD Bridge Design Specifications, 9th ed., F_{pga} equals 1.59 for Site Class E and a PGA of 0.222 g. Therefore, the A_s used in the IDOT liquefaction analysis spreadsheet was 0.353 g.

The liquefaction analyses for all boreholes are provided in the attachment. The hammer efficiency is based on SPT calibration reports provided by TSi which were conducted in August and September 2021. Both automatic hammers used by TSi during the drilling program were 94.7% efficient. For boreholes where no groundwater was observed, the depth to groundwater during an earthquake was assumed to be 4.3 ft, the highest elevation observed in 13 of the 14 boreholes. Water was observed at the ground surface at B-1N approximately 14 days after drilling, but this was deemed to be unrepresentative of the site as a whole.

As seen in the attachment, there are some layers where the IDOT spreadsheet expects more data to fully complete the analysis (cells highlighted in red). For example, in boring B-1N at an elevation of 406 ft, the spreadsheet calculated the FS against liquefaction as 3.046 but also automatically highlighted the PI (plasticity index) and LL (liquid limit) values as missing. Were these values available, the spreadsheet would check whether the PI is greater than 12 or the moisture content/liquid limit ratio is less than 0.85. If either case was true, the spreadsheet would determine the layer is "Not Liquefiable" and replace the FS of 3.046 with a statement to this effect. Either answer is acceptable from a liquefaction standpoint, i.e. regardless of whether the FS is 3.046 or the layer is "not liquefiable," the layer is not expected to liquefy in the event of a design earthquake, and the additional PI and LL data provide no added value. Laboratory tests were focused on obtaining data for layers where the initial FS was either less than or close to 1.0.

After all laboratory tests and the liquefaction analyses were complete, there were only two layers where the factor of safety against liquefaction is less than 1.0: B-2.5 at a depth of 15 ft (FS=0.994) and B-4N at a depth of 10 ft (FS=0.936). The soil layers at these locations are a low plasticity silt (PI=5) and a loose sand (N=1), respectively, which are certainly considered potentially liquefiable soils. B-2.5 is closest to Pier 7 which, according to the original 1957 drawings, is founded on concrete piles with tips located approximately 24 ft below the silt layer in a layer of dense sand (N values ranging from 14 to 39). B-4N is located closest to Pier 10 which, again according to the 1957 drawings, is founded on concrete piles with tips approximately 45 ft below the loose sand layer in what is presumably the same layer of dense sand encountered in B-2.5 (N values ranging from 17 to 26).

Since the pile tips terminate in dense sand located much deeper than the potentially liquefiable soils and since "multiple layers…indicating a FS substantially less than 1.0" (IDOT Liquefaction Analysis Design Guide) are not present, WJE does not believe that further liquefaction analysis of the site is required. If these layers do liquefy in an earthquake, we believe the existing pier foundations will still meet the IDOT performance objectives of "no loss of life or loss of span" (IDOT Liquefaction Analysis Design Guide). However, WJE recommends the temporary shoring required during the rehabilitation of the above-grade foundation elements be placed below these potentially liquefiable layers (at least 15 ft below grade).

Attachment: Completed Liquefaction Analysis Spreadsheets for B&O Bridge Boreholes

Illinois Department of Transportation

LIQUEFACTION ANALYSIS

REFERENCE BORING NUMBER ========== B-1N
ELEVATION OF BORING GROUND SURFACE ========== 416.00 FT.
DEPTH TO GROUNDWATER - DURING DRILLING ========== 25.00 FT. (Below Boring Ground Surface)
DEPTH TO GROUNDWATER - DURING EARTHQUAKE ========== 0.00 FT. (Below Finished Grade Cut or Fill Surface)
PEAK HORIZ. GROUND SURFACE ACCELERATION COEFFICIENT (As) ===== 0.353
EARTHQUAKE MOMENT MAGNITUDE ========== 5.1
FINISHED GRADE FILL OR CUT FROM BORING SURFACE ========== 0.00 FT.
HAMMER EFFICIENCY========== 95 %

SAMPLING METHOD========== Sampler w/out Liners

Groundwater was not encountered during drilling, but the spreadsheet equations cannot process a non-numerical value in this cell such as "NE." Shallower groundwater depths generally increase the FS in each layer by increasing $(N_1)_{60cs}$, so we selected a value greater than the borehole depth to remove any affect of groundwater on the $(N_1)_{60cs}$ calculation.

Lab value was 45.4%, but any value here greater than about 32% returns a negative FS. This happens because the correction for clean sand causes $(N_1)_{60cs}$ to be larger than 34. This then causes $CRR_{7.5}$ to be negative (see equation below) which makes CRR negative as well. We used a value of 32% just to show that the FS is very large and that this layer is not likely to liquefy during the design earthquake. This conclusion is also supported by the $(N_1)_{60}$ value of 24.7, which is close to the value of 25 when the spreadsheet determines the layer is non-liquefiable [N.L. (3)].

$$CRR_{7.5} = \frac{1}{34 - (N_1)_{60cs}} + \frac{(N_1)_{60cs}}{135} + \frac{50}{[10(N_1)_{60cs} + 45]^2} - \frac{1}{200}$$

* FACTOR OF SAFETY DESCRIPTIONS

Groundwater was observed at 6.7 ft depth approximately 14 days after drilling. However, we believe this shallower value is more representative of the site as a whole (and it is more conservative).

Groundwater was not encountered during drilling, but the spreadsheet equations cannot process a non-numerical value in this cell such as "NE." Shallower groundwater depths generally increase the FS in each layer by increasing $(N_1)_{60cs}$, so we selected a value greater than the borehole depth to remove any affect of groundwater on the $(N_1)_{60cs}$ calculation.

(D) = DILATIVE SOIL TYPES

Illinois Department of Transportation

LIQUEFACTION ANALYSIS

REFERENCE BORING NUMBER ========== B-6S
ELEVATION OF BORING GROUND SURFACE ========== 407.30 FT.
DEPTH TO GROUNDWATER - DURING DRILLING ========== 5.00 FT. (Below Boring Ground Surface)
DEPTH TO GROUNDWATER - DURING EARTHQUAKE ========== 4.30 FT. (Below Finished Grade Cut or Fill Surface)
PEAK HORIZ. GROUND SURFACE ACCELERATION COEFFICIENT (As) ===== 0.353
EARTHQUAKE MOMENT MAGNITUDE ========== 5.1
FINISHED GRADE FILL OR CUT FROM BORING SURFACE ========== 0.00 FT.
HAMMER EFFICIENCY========== 95 %
BOREHOLE DIAMETER========== 2.5 to 4.5 IN.
SAMPLING METHOD========== Sampler w/out Liners

EQ MAGNITUDE SCALING FACTOR
(MSF) = **2.362**

AVG. SHEAR WAVE VELOCITY (top 40')
$\bar{V}_{s,40'}$ = **239** FT./SEC.

PGA CALCULATOR
Earthquake Moment Magnitude = 5.1
Source-To-Site Distance, R (km) = 12.68
Ground Motion Prediction Equations = CEUS
PGA = **0.222**
