RE: Final Structure Geotechnical Report
Bridge Replacement
I270 over Mississippi River at Chain of Rocks
Structure No. 060-0350
Section 60B-1
Madison County, Illinois
SCI No. 2017-3167.10

Dear Mr. Riechmann:

Enclosed is our *Final Structure Geotechnical Report* dated March 2021 and revised October 5, 2021. It should be read in its entirety, and our recommendations considered in the design of the proposed bridge replacement.

This report is submitted to establish design information related to the above referenced project. The recommendations provided within the report are based on the boring and sounding locations drilled as of report date. Please call if you have any questions.

Respectfully,

SCI ENGINEERING, INC.

Final Structure Geotechnical Report

BRIDGE REPLACEMENT
I270 OVER MISSISSIPPI RIVER AT CHAIN OF ROCKS
STRUCTURE NO. 060-0350
SECTION 60B-1
MADISON COUNTY, ILLINOIS

1.0 PROJECT DESCRIPTION

The project will feature replacement of the existing bridge that carries I270 over the Mississippi River in Madison County, Illinois. The project will feature construction of a new multi-span double-structure bridge. We understand that the roadway will remain at or close to the existing elevation. A detailed grading plan was not available at the time of this report, however, we anticipated fill placement of up to 25 feet to the south for the east abutment approach to the bridge. Details regarding the extent and location of the roadway improvements will be addressed in a separate Roadway Geotechnical Report (RGR). SCI provided geotechnical engineering services for the project to include structure borings and a structure geotechnical report (SGR) for the bridge structure.

2.0 SUBSURFACE EXPLORATION

The station, offset, and elevation at each boring and sounding location were interpreted by SCI. The field exploration was performed in general accordance with procedures outlined in the *2016 IDOT Geotechnical Manual* and *2020 IDOT Geotechnical Manual* for 2018 dated borings and 2020-2021 dated borings respectively.

2.1 Drilling Exploration Methods

Sixty-six (66) standard penetration test (SPT) borings, designated B-# and BB-# were drilled for construction of the new bridge. Detailed boring locations are shown on the *Aerial Photograph*, Figures 2A-2B. Among the borings, sixty (60) borings were utilized for the design of the bridge. Also, six (6) borings (one at the west approach and five at the east approach) were drilled for use in evaluating the approach embankments. Fifty-six (56) of the structure borings were continued with rock coring techniques to evaluate the type and quality of the underlying bedrock, while the remaining four (4) structure borings were advanced to auger refusal. Auger refusal is a designation applied to any material that cannot be further penetrated by the power auger without extraordinary effort and is indicative of a very hard or very dense material, usually boulders or bedrock. Several of the structure borings were drilled during a preliminary phase of the project, prior to several interior bents being relocated. As such,

these borings no longer align with the substructure unit, but are included for complete documentation. The five (5) borings performed for the Illinois approach embankment were terminated at nominal depths ranging from 25 to 50 feet below the existing ground surface.

A Diedrich D-50 turbo drill rig, Diedrich B-57 truck-mounted drill rig, or CME-550 drill rig with hollow-stem or continuous flight augers were used to drill the borings. Samples were collected using a standard split-spoon sampler according to the methods outlined in ASTM D1586, "Standard Test Method for Penetration Test and Split-Barrel Sampling of Soils." Split-spoon samples were obtained on 2½-foot intervals in the upper 30 feet and on 5-foot intervals thereafter. In three (3) borings at the west overland section, continuous and/or full spoon (24-inches) samples were taken at the upper 10 feet to collect more samples for the determination of D_{50} (soil grain size corresponding to 50 percent finer), which is considered as one of the critical parameters for scour analysis. Shelby tube samples were collected at select locations within selected borings in place of SPT samples. Unconfined compressive strengths of cohesive split-spoon samples were measured with a Rimac testing apparatus or a pocket penetrometer when the sample was not conducive to Rimac testing. A geologist or geotechnical engineer from SCI was with the drill rig to supervise drilling, log the borings, and perform field unconfined compressive strength tests using a Rimac testing apparatus. Detailed information regarding the nature and thickness of the soils and rock encountered, and the results of the field sampling and laboratory testing are shown on the Boring Logs in Appendix A.

2.2 CPTu Exploration Methods

Additionally, a total of seven CPTu soundings (denoted as C-# on the Figures) were advanced at the approximate locations shown on the *Aerial Photograph,* Figures 2A through 2B, and *Site Plan,* Figure 3A through 3E. The site is in the flood plain and the geology features interbedded fluvial deposits and sand, silt and clay. The CPTu locations were selected to assess the range of properties in these deposits. The CPTu soundings were conducted in accordance with ASTM D5778 "Standard Test Method for Performing Electronic Friction Cone and Piezocone Penetration Testing of Soils." The equipment used was a Vertek Scorpion S4 mounted on a trailer.

The trailer rig is equipped with two auger anchors which, when deployed, can provide up to 20 tons of down pressure reaction. Refusal is determined when the anchors fail or pull from the ground. Alternatively, refusal can be achieved when the pressure tolerances of the cone are exceeded. This is indicated by a warning message when performing a sounding. Refusal to penetration is indicative of very dense or hard material, typically bedrock, boulders, or debris.

The CPTu hydraulically pushes an instrumented cone through the soil while continuous readings are recorded on a portable computer. The cone is advanced through the ground at a constant rate of 2 centimeters per second (2 cm/sec). Load cells or strain gauges within the cone measure the in-situ parameters of the soil: tip resistance, friction and pore water pressure. These in-situ measurements of tip, side resistance, and porewater pressure are recorded every 2 centimeters (approximately 1 inch). These measurements are an evaluation of soil strength, which is used to interpret how they will behave due to loading.

The *CPTu Logs* in Appendix B of this report graphically illustrate the relative strength of the soils encountered and provide an approximate soil stratigraphy. Stratification lines on the *CPTu Logs* represent approximate boundaries between ***soil behavior types*** based on accepted correlations between the tip, side, and porewater pressure measurements.

2.3 Laboratory Procedures

Advanced laboratory testing was conducted to classify the samples, determine index properties, and characterize the soil's behavior. These tests include:

- Sieve Analysis / Grain Size Analysis (ASTM D422);
- Sieve Analysis / Wash <#200 (ASTM D1140);
- Unconfined Compressive Strength testing (ASTM D2166);
- One Dimensional Consolidation (ASTM D2435);
- Classification of Soils for Engineering Purposes (USCS) (ASTM D2487);
- Visual Soil Classification (ASTM D2488);
- Unconsolidated Undrained Triaxial (ASTM D2850);
- Unit Weight Determination (ASTM D2937);
- Atterberg Limits (ASTM D4318);
- Moisture Content (ASTM D4959);
- Unconfined Compressive Strength of Rock Core Specimen (ASTM D7012); and
- Sieve Analysis / Hydrometer (ASTM D7928).

The results of the laboratory testing are included on the Boring Logs in Appendix A and are also included as separate sheets within Appendix A.

2.4 Generalized Subsurface Profiles

The following sections summarize the subsurface soil conditions encountered within each of the borings and are broken up into defined project areas along the bridge alignment. The subsurface profiles are graphically presented in Figures 4A through 4E.

2.4.1 West Abutment

The overburden encountered in borings within this region of the project (BB-01, BB-02 and B-101) generally consisted of 3 to 20 feet of fill, consisting of silt, clay, and loam with various amounts of sand and crushed rock. The fill was medium stiff to stiff in consistency. Borings B-101 and BB-02 were drilled at the base of the embankment and do not include the full height of the embankment fill. BB-01 was drilled through the bridge deck and near the top of the embankment. Beneath the fill are interbedded natural deposits of clay (A-6 and A-7) and silt (A-4) to depths of approximately 28 to 33 feet (El 389.6 to 377.6). The native soils were generally very soft to medium stiff in consistency. In boring B-101, the overburden soils were underlain by a gray clayey shale, which extended to a nominal depth of 38.8 feet (El 381.3). Beneath the shale and the overburden, boring B-101 encountered weathered limestone bedrock with interbedded clayey shale seams, which extended to the termination of boring at depth of 41.5 feet (El 377.6). Auger refusal was encountered at the termination depths of all three borings. Auger refusal is indicative of very dense or hard material, which is typically bedrock, boulders, or debris. No rock coring was performed beyond the auger refusal depth in these borings.

Groundwater was encountered during drilling in all three borings at depths ranging from 3.5 to 27.5 feet (El 415.6 to El. 409.6). Based on the proximity to the Mississippi River, we anticipate that the groundwater elevation will be highly influenced by the elevation of the river.

2.4.2 West Over-Land Section

The overburden encountered in two borings (BB-03 and BB-05) drilled for this section generally consisted of 11 to 20 feet of fill, consisting of very soft to medium stiff silt to silty clay and loam with various percentage of sand. These borings were also drilled at the base of the embankment and do not include the full height of the embankment fill. Boring BB-03 was drilled through the bridge deck while BB-05 was drilled directly from the ground surface underneath the existing bridge. The fill layer was underlain by the natural soils consisting of clay loam (A-6) and sandy loam (A-2) down to the auger

refusal depth of boring BB-03 at approximately 33.5 feet (El 386.5). Similarly, the natural soils in boring BB-05 consisted of silt (A-4) to silty loam and clay (A-6) with various amounts of sand to the refusal depth at approximately 36 feet (El 384.4).

The limestone bedrock was cored using NQ wireline rock coring methods to a nominal depth of 30 feet into bedrock at both locations. The recovery was 100 percent for all the rock core runs. The RQD ranged from 76 to 98 percent, with an average RQD value of 84 percent. The overall rock quality ranged from Good to Excellent and was generally Good. The uniaxial compressive strength on select rock core samples ranged from 350 to 911 tsf with an average strength of approximately 616 tsf.

Groundwater was not encountered in boring BB-03 while it was encountered after drilling at 34.1 feet (El 386.3) in boring BB-05. Based on the proximity to the Mississippi river, we anticipate that the groundwater elevation will be highly influenced by the elevation of the river.

2.4.3 Over-Water Section

For the over-water section, thirty-five (35) bent locations were explored. Borings BB-23, BB-36, and BB-38 had to be offset once while BB-16 had to be offset twice to drill them down to the planned depth. The depths to mudline within the Mississippi River varied from 2.1 to 37.2 feet. The mudline soils at the river bottom generally consisted of very soft silts and clays, very loose sands, and gravels and extended to depths ranging from 0.7 to 28.5 feet below the mudline. The mudline soils at all boring locations were underlain by limestone bedrock. As an exception, the bedrock was encountered at the river bottom without any mudline soils in borings BB-10 and BB-12. The bedrock generally appeared to dip towards the east with its top elevations ranging from 391.5 feet (at BB-08 on the west end) down to 340.7 feet (at BB-34 on the east end).

The limestone bedrock was cored using NQ wireline rock coring methods to a nominal depth of 30 feet into bedrock at all the locations except BB-10, BB-16A, BB-16B, BB-23, and BB-36 where the coring was stopped at a shallower depth due to drilling issues (tool breakage, casing movement resulting in binding due to river flow, etc…). The recovery ranged from 38 to 100 percent with an average recovery of 96 percent. The RQD ranged from 0 to 100 percent, with an average RQD value of 80 percent. The overall rock quality ranged from Very Poor to Excellent and was generally Good. The uniaxial compressive strength on select rock core samples ranged from 212 to 1,404 tsf with an average strength of approximately 693 tsf.

2.4.4 East Over-Land Section

The overburden encountered in the over-land generally consisted of interbedded colluvial deposits to depths ranging from 4 to 34 feet (elevation 417.4 to 376.8 feet). The upper colluvial soils consisted of sandy silts (A-4), silty to sandy clays, (A-6 and A-7) and clays (A-7). The fine-grained materials were very soft to stiff and were typically soft in consistency. Beneath the upper soils are silty to clean sands (A-1 and A-2) with various amounts of gravel, which extend to the top of bedrock. The bedrock depth varied from 71 to 81.6 feet and its top elevations from 327.2 to 345.1 with an average depth of 76.5 and average elevation of 337.6. The depth of rock tended to be deeper as the alignment moved to the east. Weathered limestone was encountered within seventeen (17) of the twenty (20) borings within this section and ranged in thickness from 0.8 feet to 5.0 feet with an average thickness of 2.1 feet.

The limestone bedrock was cored using NX rock coring methods an additional 15.5 to 40 feet beyond auger refusal in seventeen (17) of the twenty (20) borings within this section. The recovery ranged from 0 to 100 percent with an average recovery of 95 percent. The RQD ranged from 0 to 96 percent, with an average RQD value of 57 percent. The uniaxial compressive strength on random rock core samples ranged from 208 to 1,413 tsf with an average strength of 789 tsf. The overall rock quality ranged from Very Poor to Excellent and was generally Fair.

Groundwater was encountered during drilling in several of the borings at elevations ranging from 409 to 397.8 feet with an average elevation of 403.7 feet. Based on the proximity to the Mississippi River, we anticipate that the groundwater elevation will be highly influenced by the elevation of the river.

2.4.5 East Approach and Abutment

The overburden encountered in the east approach abutment area generally consisted of fill underlain by interbedded colluvial deposits to depths ranging from 8 to 34 feet (El 398.5 to 417.4) with an average depth of 20 feet (El 409.2). The upper colluvial soils consisted of sandy silts (A-4), silty to sandy clays, (A-6 and A-7) and clays (A-7). Generally, the deeper surficial deposits were associated with the existing I-270 embankment, which is approximately $\pm$22 feet higher in elevation than the surrounding ground surface. The fine-grained materials were soft to stiff and were typically medium stiff in consistency. Beneath the upper soils are silty to clean sands (A-1 and A-2) with various amounts of gravel, which extend to the top of bedrock. The bedrock depth varies from 95.3 to 96.0 feet (El 330.9 to 331.3) with an average depth of 95.7 (El 331.1). Weathered bedrock was encountered within both deep borings that encountered limestone and ranged in thickness from 0.4 feet to 0.7 feet with an average thickness of 0.5 feet. The limestone bedrock was not cored at the abutment or approach embankment locations.

Groundwater was encountered during drilling in several of the borings and CPTu soundings at depths ranging from 8 to 41 feet (El 401 to 413.9) with an average depth of 17.9 feet (El 406.7). Based on the proximity to the Mississippi River, we anticipate that the groundwater elevation will be highly influenced by the elevation of the river.

3.0 GEOTECHNICAL EVALUATIONS

In order to provide design recommendations for supporting the structures, we performed the following evaluations based on all available data collected and reviewed at the time of this report. This information includes subsurface explorations performed by SCI, preliminary TS&L plans, and communications with Horner & Shifrin, Inc. (H&S) and Parsons Transportation Group (PTG) personnel familiar with the project. The preliminary TS&L is attached to the SGR as Appendix G.

3.1 Seismic Considerations

3.1.1 Design Earthquake

For the purposes of seismic design, the bridge has been classified as *Critical*. According to the Illinois Department of Transportation, the structure should be designed to a design earthquake with a 2 percent Probability of Exceedance (PE) over a 50-year exposure period (i.e. a 2,500-year design earthquake). According to the procedures outlined in the All Geotechnical Manual Users (AGMU) 10.1, *Liquefaction Analysis Procedure,* and data provided by the United States Geological Survey (USGS) National Seismic Hazard Mapping Project, the design earthquake has a Moment Magnitude (Mw) of 5.3 and a Peak Ground Acceleration (PGA) of 0.48, for the purposes of evaluating the liquefaction potential at the project site.

3.1.2 Site Class Determination

The seismic site soil classification for the bridge site was determined from the design earthquake data, the subsurface data, and the procedures described in the AASHTO Bridge Manual with modifications from IDOT Bureau of Bridges and Structures (BBS) [Refer to the Structural Design Criteria, dated May 2020 for additional information]. The Site Class was evaluated using methods defined as A, which include evaluating the shear wave velocity (Vs) profiles for the site. Generally, method A is considered the most accurate method of determining the soil site class and is typically required when bedrock is encountered at a relatively shallow depth. For the overwater section, the drilled shaft foundations are assumed to be supported entirely within the underlying bedrock as the resultant scour would remove a majority of the soft underconsolidated soils encountered at the river bottom. For this section, the average shear wave

velocity was measured on each side of the river and only the values measured within the limestone were considered as representative for the limestone bedrock within the river. The results of this evaluation are summarized in Table 3.1. Seismic design parameters are summarized in Tables 3.2A through 3.2C.

Table 3.1 - Site Class Determination Results for Various Structure Segments

Section	Weighted Average Vs (ft/sec)	Site Class
West Approach (Unit 1 – W. Abut, Piers 1 to 3)	1,430	C
Overwater section (Units 2&3 – Piers 4 to 16)	3,600	AB
Over-Land/East Approach (Units 4&5 – Piers 17-25, E. Abut)	1,025	CD

Table 3.2A – Seismic Design Parameters for West Approach

Seismic Design Parameters	
Site Class	C
Design Spectral Acceleration at 0.2 sec (S_{DS})	0.608
Design Spectral Acceleration at 1.0 sec. (S_{D1})	0.204
Site Coefficient (As)	0.303
Seismic Performance Zone	2
Seismic Design Category	D

Table 3.2B – Seismic Design Parameters for River Section

Seismic Design Parameters	
Site Class	AB
Design Spectral Acceleration at 0.2 sec (S_{DS})	0.465
Design Spectral Acceleration at 1.0 sec. (S_{D1})	0.153
Site Coefficient (As)	0.307

Design Spectral Acceleration at 0.2 sec (S_{DS})	0.668
Design Spectral Acceleration at 1.0 sec. (S_{D1})	0.279
Site Coefficient (As)	0.300
Seismic Performance Zone	2
Seismic Design Category	D

3.1.3 Liquefaction Potential Analysis

The analysis to assess the liquefaction potential for the site was conducted in general accordance with the guidelines outlined in AGMU 10.1. The analysis was conducted using the soil test boring data, as well as the CPTu and shear wave velocity data collected for the project as well. The soil test boring data was analyzed initially using the IDOT-developed spreadsheets. All of the sources of information were then evaluated using the software program, *CLiq and LiqSVs* published by Geologismiki Geotechnical Software. The software program utilizes up to five different state-of-practice methods for evaluating CPTu data and two different methods for evaluating soil test boring and shear wave velocity data. In addition to evaluating the potential for liquefaction, the program offers tools to evaluate the overall probability of liquefaction occurring as well as the range of settlements possible.

To better understand the dynamic behavior of the soils, we performed a two-phase approach. The first phase was a basic liquefaction potential analysis, while the second phase was a broader risk assessment. The overall risk assessment consisted of a parametric study to evaluate the probability of liquefaction utilizing all the various methods and available data, and the potential outcome if liquefaction were to occur. The results of the liquefaction analysis are provided in Appendix C2.

For seismic hazard evaluations, it is generally not prescribed to assume that earthquakes would coincide with other extreme loading events, (i.e. reoccurring flood events). The average seasonal groundwater elevation used in the analysis was estimated from the typical pool elevation of the Mississippi River. This was done by evaluating 13+ years of river elevation data available for the St. Louis gage, which was the primary gage referenced for the geotechnical portions of the project. This “median” pool elevation was then adjusted up 7.51 feet to account for the distance upstream from the gage to the project site. The value was derived by measuring a surface elevation of the water at the project site and comparing it to the gage reading at that time. Based on the data, the mean elevation of 402.6 was utilized for the

overall liquefaction analysis. This elevation corresponds to a flood stage height of approximately 15.5 at the St. Louis gage. Additionally, for the initial evaluation using the IDOT spreadsheets, an elevation approximately 4 feet higher was selected to provide a conservative first estimate of liquefaction potential.

Sands located above the groundwater table are not susceptible to liquefaction. Additionally, research has shown that liquefaction below 50 to 60 feet is unlikely to occur except for rare instances. Guidance within the CLiq manual indicates that 50 feet is typically adequate stating "*Experience has shown that the 50-foot (15-m) depth may be adequate for the evaluation of liquefaction potential in most cases, however, there may be situations where this depth may not be sufficiently deep."* The California Department of Transportation guidelines for Liquefaction Evaluation and DMG Special Publication 1171 [1](SP117) "*Recommended Procedures for Implementation of Guidelines for Analyzing and Mitigating Liquefaction Hazards in California,"* reiterate this guidance and require a minimum depth of investigation of 50 feet below finished grade when evaluating for liquefaction unless deep foundations or below grade structures may be influenced, at which point deeper investigations may be required. For the purposes of this analysis, the lower limit of liquefaction was set at 50 feet below existing grades as all the foundations will penetrate the overburden soils and bear on or in the underlying bedrock.

Based on our analyses, most of the soils have sufficient strength and/or a plasticity index that make the threat of liquefaction minimal during the design earthquake. However, isolated relatively thin (~5 feet or less) layers of loose sands encountered at the top of the sand layer may be susceptible to liquefaction during a design event. The potentially liquefiable soils were encountered within a portion of the bridge borings evaluated. A majority of the occurrences happened just below the groundwater table surface, where it's possible that sample disturbance and differential head condition may have existed at the time of sample collection. This can sometimes result in SPT N-values being lower than actual. Additionally, some deeper occurrences of isolated liquefaction were predicted as well.

As part of the hazard analysis, SCI considered the probability that the soils would liquefy during the design event based on three indices: Liquefaction Probability Index (LPI), Liquefaction Severity Number (LSN), and the overall probability to liquefy. Then from that, an estimate of potential settlements is predicted if liquefaction were to occur. The methods assess the overall likelihood of the soils liquefying as well as the likelihood of the liquefaction manifesting itself as a surface disruption. Table 3.3 presents the ranges and values for each index.

[1] Arulmoli, K, Baez, J.I., Blake, T.F., Earnest, J., Gharib, F., Goldhammer, J., Hsu, D., Kupferman, S., O'Tousa, J., Real, C.R., Reeder, W., Simantob, E., and Youd, T.L. (1999), "Recommended Procedures for Implementation of DMG Special Publication 117 Guidelines for Analyzing and Mitigating Liquefaction Hazards in California."

Table 3.3 – Summary of Scale for Probability Analysis Results

Probability		Liquefaction Probability Index (LPI)	
0 to 12	Low Probability	0 to 5	Minor/Low
12 to 55	High Probability	5 to 15	Moderate/Medium
>55	Very High Probability	>15	Major/High

For the CPTu testing data, the four primary soundings were evaluated using five different methods for estimating liquefaction potential, for a total of twenty data points.

When considering the probability, 15 of the 20 total iterations, or 75 percent, fell below 12, indicating a low probability of liquefaction even occurring. Of the five iterations to fall within the range of high probability, four of the occurrences were associated with soundings C-107 and C-118. Similarly, for the LPI, 33 of 39 iterations, fell into the low risk category with a value below 5. The six remaining analyses fell in the range between 5.5 and 14.5 were again four of the instances were associated with sounding C-107 and C-118. While evaluating the LSN, which is an indicator of the level of severity of the effects of liquefaction, 37 of 39, or 95 percent, fell within a range of little to minor impacts. The remaining two instances fall within the range of moderate to severe impacts, but are also only associated with a single sounding, C-118. When evaluating the potential outcome of the liquefaction, the parametric study indicated that in 31 of the 39 iterations, the predicted settlement was less than 2 inches, while the remaining eight iterations ranged from 2.1 to 5.1 inches. The four highest predictions of settlement occurred within four of the soil test borings, that also had a low probability of occurrence.

As previously referenced, it is anticipated that all of the piles and/or drilled shafts will extend through the potentially liquefiable soils and bear on or in the underlying bedrock. Additionally, the unbraced length of the piles during liquefaction should not be a concern as the potentially liquefiable layers are relatively thin (less than 5 feet thick) and do not uniformly occur across the site. While the amount of the seismically-induced settlement is dependent on the magnitude and distance from the seismic event, SCI estimates that the impacts from the design earthquake will be negligible.

3.2 Abutment Approach Settlement

Preliminary information provided by Horner & Shifrin, Inc. indicated up to 25 feet of fill could be placed near the west and east abutment approaches. The following preliminary evaluations are based on the data obtained in the STBs and CPTs performed in the vicinity of the approach embankments.

3.2.1 East Abutment

Based on the soils encountered in the STBs and CPTs performed within the proposed footprint of the east embankment, settlement due to the additional fill placed along the south side of the existing east approach abutment was estimated to be less than 1 inch. Although the predicted settlement is greater than the 0.4 inch typically used by the Department as a limiting value for effecting the structure, based on the stiffness of the soils, the settlement will be primarily elastic deformation and will occur prior to placing the bridges in operation. To minimize the effects of settlement on the embankment approach slab, we recommend the eastern embankment should be constructed and in place a minimum of 120 days prior to constructing the approach slabs or performing final paving. Due to the elastic nature of the estimated settlement and the fact that the abutment piles will be installed to the top of rock, downdrag effects on the piles for the east abutment bay be neglected.

3.2.2 West Abutment

After the beginning of the project, it was determined that the west approach embankment would be included within the design of the Riverview Drive project as that project already included a large portion of the approach embankment and associated ramps. Based on that report, by others, dated May 2020, settlement due to the new fill could range up to 10 inches. The report also indicates a majority of the settlement could take up to 12 months. To minimize the effects of settlement on the structure (i.e. abutment foundations), we recommend the approach embankment be constructed and in place a minimum of 270 days prior to constructing the approach slabs. Based on the anticipated settlement time, the effects of downdrag should be considered in the design of the piles for the west abutment. Also, as an alternative, the pile locations could be pre-cored through the soil layers contributing to downdrag. However, pre-coring would need to terminate near the top of bedrock at a nominal elevation of 389. Downdrag effects on the piles due to settlement are addressed further in the Bridge Foundation Section of this report.

3.3 Bridge Approach Slabs

The bridge approach slabs should be designed to bear on existing embankment fill or newly placed low plastic structural fill. In evaluating the bearing resistance of the slabs, we recommend using a modulus of subgrade reaction of 150 pounds per square inch per inch of deflection (pci). Based on the planned fill height and the soils encountered at abutments, we do not anticipate any bearing capacity concerns for the approach slabs.

3.4 Slope Stability

The global slope stability of the east approach embankment was analyzed for end-of-construction (short-term), long-term, and seismic (pseudo-static) loading conditions, at two cross-sections, as shown on Figure 3. The analyses were conducted using limit equilibrium slope stability methods and the commercially available software program Slide 2018 (developed by Rocscience, Inc.). The analyses considered soil properties from the subsurface exploration data, and the given slope geometries. To account for traffic loading, a surcharge load of 250 psf was applied to the analyses. For the seismic evaluation, the peak ground acceleration (PGA) from the design earthquake along with procedures for seismic slope stability outlined in Federal Highway Administration (FHWA) publication FHWA-HI-99-012 *Geotechnical Earthquake Engineering* were utilized. Soil parameters used in the analyses and the results of the analyses are shown on the output plots in Appendix C3.

A Morgenstern-Price analysis with a circular mode of failure was used to search for the critical factor of safety (FS). The required minimum factors of safety were obtained from Section 6.10.4 of the 2020 IDOT Geotechnical Manual for the global slope stability. The results of the global slope stability analyses are presented in Table 3.4 below.

Table 3.4 – Summary of Estimated Global Slope Stability Factors of Safety

Analyzed Cross-section	Short-Term Static Condition		Long-Term Static Condition		Seismic Condition	
	Required FOS	Estimated FOS	Required FOS	Estimated FOS	Required FOS	Estimated FOS
A-A	1.3	2.2	1.3	1.6	1.0	1.1
B-B	1.3	2.6	1.3	1.7	1.0	1.7

3.5 Scour Considerations

We understand that scour protection will be provided at the bridge abutments and along the roadway embankments. Therefore, data to be used in evaluating scour in these areas was not evaluated, nor should it affect the project during the lifespan of the structure.

We understand that scour may occur adjacent to the Mississippi River bridge bents to the depth of rock. Additionally, we understand that the bridge bents founded on land will be susceptible to scour. To evaluate the potential scour elevation, the particle size distribution of select samples collected within the upper 40 feet of the landside bridge bents were measured. The D95 and the D50 were determined using Sieve Analysis / Grain Size Analysis (ASTM D422) and Sieve Analysis / Hydrometer (ASTM D7928). The D95 corresponds to the particle size greater than 95 percent of all of the particle sizes within the sample by weight. The D50 value corresponds to the median grain size, by weight. This sieve analysis data is presented in Appendix A. Based on the provided TS&L, the design scour elevations for the 100-year and 200-year events for the abutment and interior bents are shown in Table 3.5 below.

Table 3.5 – Summary of Design Scour Elevations

Pier	Eastbound Bridge		Westbound Bridge

Item 113	5		5	

3.6 Bridge Foundations

The foundation supporting the proposed bridge must provide sufficient support to resist dead and live loads, including seismic loads. Two potential foundation options were considered for supporting the new bridge structure that include driven steel H-piles at the abutments and drilled shafts socketed into bedrock for the interior bents. For the driven pile option, we recommend a minimum of one test pile be installed for each abutment to verify capacity and overall pile length. Recommendations for all the potential foundation options are provided below.

3.6.1 Driven Steel Piles

The structural capacity of driven piles depends on the allowable stress and cross-sectional areas of steel. The pile recommendations in this report assume that Steel H-piles will conform to AASHTO M270 Grade 50 (ASTM 709 Grade 50) or equivalent with a minimum yield stress of 50 kips per square inch (ksi).

Based on the Bridge Manual, a geotechnical resistance factor (φ_G) of 0.55 was used for the design of the H-pile foundations. Due to the potential for downdrag on the west abutment we recommend the use of bond breakers or pre-coring, as previously discussed, to reduce the effects of downdrag on the piles. Tables for both downdrag and no downdrag are included in the pile design tables in Appendix E. For the east abutment, geotechnical losses associated with down-drag due to settlement were not considered during the static and seismic pile design for the abutment piles. Although isolated liquefaction is a potential concern, geotechnical losses due to liquefaction were not considered in the seismic pile design (see discussion presented in Section 3.1.3 Liquefaction Potential Analysis). During the seismic event, the Bridge Manual allows the use of a Geotechnical Resistance Factor (φ_G) of 1.0. All estimates of capacity were calculated using the "Modified IDOT Static Method" spreadsheet associated with the Bridge Manual and assume construction verification will follow the "WSDOT" formula outlined in the Bridge

Manual. The top elevations of the piles were obtained from the information provided by H&S on the preliminary TS&L included in Appendix G. The tip elevations were calculated from the Modified IDOT Static Method spreadsheets based on the available factored resistance.

SCI recommends a minimum driven pile center-to-center spacing of three pile diameters, as recommended by the Bridge Manual. The maximum spacing shall be limited to 3.5 times the effective footing thickness plus 1 foot, but not to exceed 8 feet. Once the final spacing is determined, the piles should be evaluated for group effects.

A summary of the design capacities, or factored resistance available (R_F), seismic factored resistance (R_{Fseis}), and nominal required bearing (RN) is presented in Appendix E for each steel pile size. The summary of estimated maximum drivable pile length is given below in Table 3.6.

Table 3.6 – Summary of Estimated Pile Lengths

Pile Type and Size	Estimated Maximum Pile Length (feet)		$R_{N\ max}$ (kips)
	West Abutment	East Abutment	
Steel HP 12×53	55	106	419
Steel HP 12×63	56	106	497
Steel HP 12×74	56	112	589
Steel HP 12×84	57	112	664
Steel HP 14×73	56	111	578
Steel HP 14×89	56	112	705
Steel HP 14×102	57	113	810
Steel HP 14×117	58	113	929

SCI was provided with the foundation loads for HP piles for both Eastbound and Westbound structures in July 2021 and are summarized in Table 3.7 below.

Table 3.7 – Summary of Foundation Loads for HP Piles

	West Abutment	East Abutment	
Total Factored Substructure Load - LRFD	2800	2500	[kip]
Total Factored Substructure Load - SEISMIC	1700	1700	[kip]
Total Length of Substructure (along skew)	68.326	60.146	[ft]
Number of rows of piles per substructure	2	2	

3.6.2 Drilled shafts

We anticipate that drilled shaft foundations will be suitable to support the river bents and the interior land bridge bents. For the purpose of determining the economic feasibility for the drilled shaft option, the factored tip resistance and/or a factored skin friction are provided in the summary design tables detailed in Appendix F. Drilled shafts should be spaced no closer than three shaft diameters, center to center. Due to the observed groundwater table, and the sands and gravels encountered during our exploration, casing will be required in the soil to prevent collapsing of the side walls during installation. Drilled shafts for the interior bents should be socketed into bedrock. It is not anticipated that drilled shafts would be used at that abutment locations.

The values presented in Appendix F reflect a geotechnical resistance factor (φ_G) of 0.50 for tip resistance and 0.55 for skin friction, for strength limit design. For seismic considerations, a (φ_G) of 1.0 should be used to calculate the seismic factored resistance available (R_{fseis}). Foundation loads for a single drilled shaft at each pier location were provided to SCI in July 2021 are summarized in Table 3.8 below.

Table 3.8 – Summary of Foundation Loads on a Single Drilled Shaft

Pier	Extreme [kip]	Strength [kip]	Service [kip]
Pier 1	3000	3200	2500

Pier 23	4600	5000	3600
Pier 24	4000	4200	3200
Pier 25	5200	4800	3600

3.6.2.1 Drilled Shaft QA/QC and Construction Considerations

A construction method using a casing for the interior bents will be required due to the various sand layers that were encountered during the investigation. The auger cuttings should be observed as the shafts are drilled to document that competent materials are present. QA/QC for the drilled shafts should include a combination of using a shaft inspection device (SID camera) to ensure the bottom is clean and the socket is uniform and stable. This will also verify that the estimated uplift capacities are present. Crosshole Sonic Logging (CSL) testing should be performed to verify the integrity of the concrete after placement.

3.7 Lateral Pile Response

A representation of the shaft response under lateral loading exceeding 3 kips per pile is required for design of the bridge superstructure per Section 3.10.1.10 of the 2009 Bridge Manual. The lateral response can be developed by modeling the soil/shaft interaction with the computer program LPILE. Discrete elements are used in LPILE to represent the shaft and non-linear soil using springs. The non-linear soil springs are commonly referred to as P-Y curves.

Based on the encountered subsurface conditions, tables summarizing approximate soil modulus parameters (k) for the LPILE analyses at each boring are included in Appendix D (Reference: LPILE User's Manual, Ensoft, Inc., 2019). When pile/shaft design details and load information are refined in the development of the structure plans, LPILE analyses, if warranted, can be performed.

4.0 CONSTRUCTION CONSIDERATIONS

The construction activities should be performed in accordance with the current *IDOT Standard Specifications for Road and Bridge Construction* and any pertinent Special Provisions or policies. We anticipate that temporary sheeting, including cantilever temporary sheet piling, will be feasible according to *Section 3.13.1 – Temporary Sheet Piling Design*. As such, staged construction will be required for this project. Temporary sheeting will have an anticipated maximum retained height of 12 feet. A minimum embedment depth of 18 feet with a minimum section modulus of 25 cubic inches per foot should be used for planning purposes.

A Hydraulic No-Rise during construction shall be maintained. The removal of the existing substructure below ground is assumed to be removed using construction barges with excavators with concrete breakers and processors. Broken pieces of concrete are allowed to settle to the bottom of the river prior to removal from the site. The use of cofferdams for pier removal will need to be approved to ensure the hydraulic no-rise condition will be met.

Placement of the rip rap scour protection in front of the west abutment may encounter very soft soils, which may be difficult to work on and retain the rip rap. If this condition is encountered, a combination of excavation and replacement along with the use of a geotechnical separation fabric can be utilized to create a stable subgrade. The excavation may extend to a depth of 2 to 4 feet and the geotechnical separation fabric placed on the subgrade. Approximately 2 feet of 4-inch minus material could be placed on the fabric to create a stable platform. The crushed rock should be completely encapsulated with the filter fabric. The rip rap could then be placed on top of the crushed rock mat to design grades. The amount of undercut may be adjusted, either up or down, based on the river elevation at the time of construction.

5.0 LIMITATIONS

The recommendations provided herein are for the exclusive use of our client, Horner & Shifrin, Inc. and IDOT. They are specific only to the project described, and are based on subsurface information obtained at the boring locations performed for the project, our understanding of the project as described herein, and geotechnical engineering practice consistent with the standard of care. No other warranty is expressed or implied. SCI should be contacted if conditions encountered during construction are not consistent with those described.

SHELBY TUBE TEST RESULTS

Date 12/08/18

ROUTE FAI 270 **DESCRIPTION** I-270 over the Mississippi River **DRILLED BY** GeoServices, Inc.

SECTION 60B-1 **LOCATION** East Approach, **SEC.** 36, **TWP.** 4N, **RNG.** 10W

COUNTY Madison **STRUCT. NO.** 060-0350 (EB)
Station 806+89.23

BORING NO. B-112
Station 1838+95.92 **Ground Surface Elev.** 442.2 ft **Tube Length** ____ in
Offset 12.4 ft L (EB) **Begin Sampling Depth** -11 ft **Tube Diameter** ____ in

SOIL TYPE, DESCRIPTION, AND OBSERVATIONS	DEPTH (ft)	SPECIMEN (no)	RECOVERY (%)	UNIT WEIGHT (pcf)	STRENGTH (tsf)	MOISTURE (%)	TRIAXIAL DATA: COHESION (tsf)	TRIAXIAL DATA: PHI ANG. (deg)	TRIAXIAL DATA: TEST TYPE
Clay Loam: Gray, moist, fill, A-4.		ST-1	46	128		20			
	-15								
	-20								

The "Unit Weight" column indicates the "wet" or "moist" unit weight of the sample.
The "Strength" column represents the "unconfined compressive" strength of the sample (AASHTO T 208).
The "Test Type" indicates if Unconsolidated Undrained (UU) or Consolidated Undrained (CU) test procedures (AASHTO T 296 or T 297) were used.

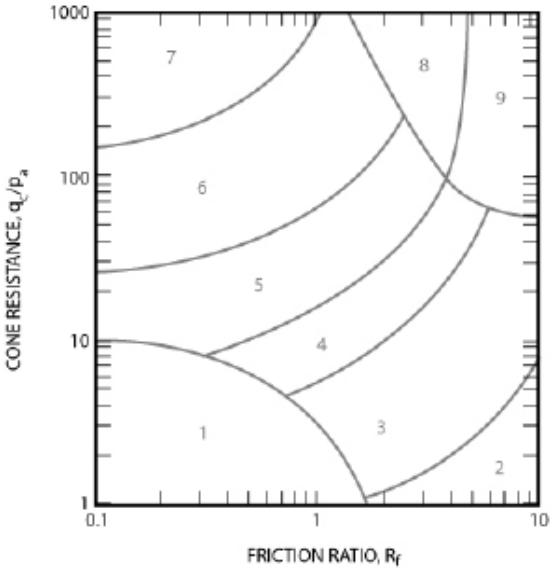
www.sciengineering.com

USE and UNDERSTANDING of CPTu Logs

The CPTu logs show the corrected Tip Resistance (q_t), Friction (f_s), Porewater Pressure (U_2), SPT N_{60} correlation (N_{60}), and the Soil Behavior interpretation results. The corrected cone tip resistance (q_t) is measured as the maximum force over the projected area of the cone tip. It is a point stress related to the bearing capacity of the soil. The measured uncorrected tip value (q_c) must be corrected for porewater pressure effects (Lunne et al, 1997), especially in clays and silts where porewater pressures typically vary greatly from hydrostatic. The sleeve friction (fs) is used as a measure of soil type and can be expressed by friction ratio (R_F) which is used in the soil behavior classification. The u_2 position element is required for the measurement of penetration porewater pressures and the correction of tip resistance. Calculations of q_t, R_F, and the SPT N_{60} calculation are discussed below.

The estimated stratigraphic profiles included in the CPTu logs are based on relationships between q_t, f_s, and U2 as shown graphically in the figure below.

Non-normalized CPT Soil Behavior Type (SBT) chart



Z	*Soil Behavior Type*
1	*Sensitive, fine grained*
2	*Organic soils - clay*
3	*Clay – silty clay to clay*
4	*Silt mixtures – clayey silt to silty clay*
5	*Sand mixtures – silty sand to sandy silt*
6	*Sands – clean sand to silty sand*
7	*Gravelly sand to dense sand*
8	*Very stiff sand to clayey sand**
9	*Very stiff fine grained**

** Heavily overconsolidated or cemented*

P_a = atmospheric pressure = 100 kPa = 1 tsf

Derived Values from CPT

Corrected cone resistance: $q_t = q_c + u_2(1-a)$
Friction ratio: $R_f = (f_s/q_t) \times 100\%$

Equivalent SPT N60, (blows/ft) Lunne et al. (1997)

$$\frac{(q_t/p_a)}{N_{60}} = 8.5 \times \left(1 - \frac{I_c}{4.6}\right)$$

Where $I_c = ((3.47 - \log Q_{t1})2 + (\log R_F + 1.22)2)0.5$
And $Qt_n = ((q_t - sv_o)/p_a) \times (p_a/(s'v_o)n$, and
recalculate I_c, then iterate for n:

$$n = 0.381 \times I_c + 0.05 \times \left(\frac{s_{vo}'}{p_a}\right) - 0.15$$

Iterate until the change in n, $\Delta_n < 0.01$

SPT BASED LIQUEFACTION ANALYSIS REPORT

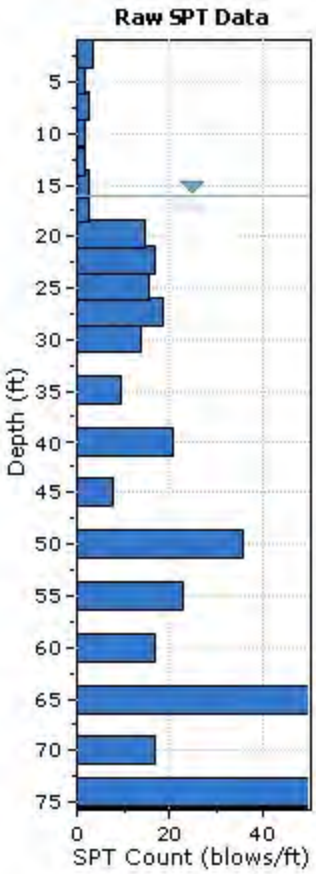
Project title : I-270 Bridge over COR

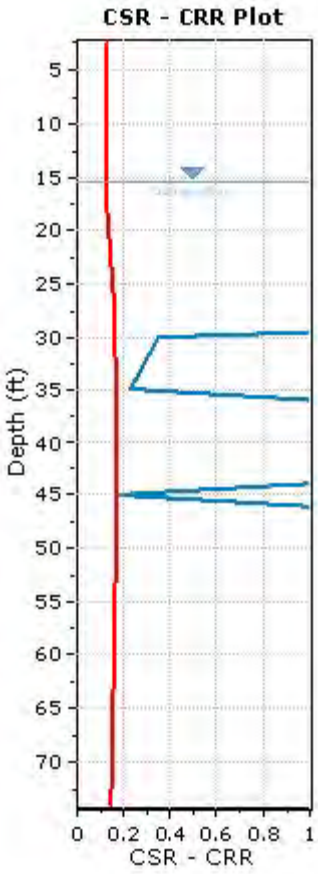
SPT Name: BB-29

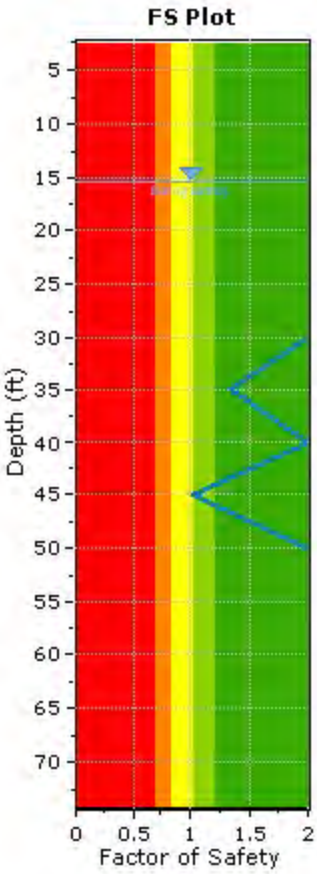
Location : Madison County, Illinois

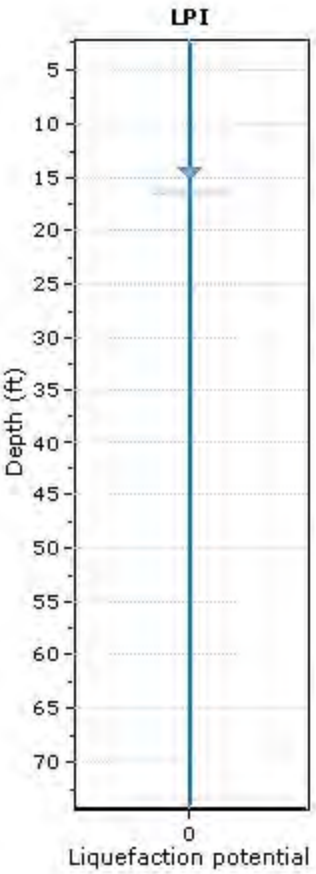
:: Input parameters and analysis properties ::

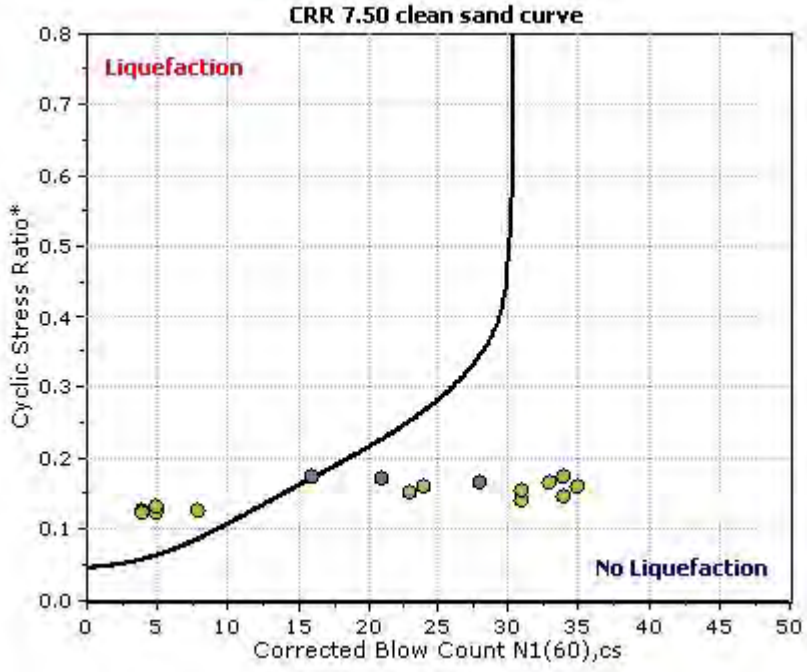
Analysis method:	NCEER 1998	G.W.T. (in-situ):	16.00 ft
Fines correction method:	NCEER 1998	G.W.T. (earthq.):	15.40 ft
Sampling method:	Standard Sampler	Earthquake magnitude M_w:	5.30 ft
Borehole diameter:	65mm to 115mm	Peak ground acceleration:	0.48 g
Rod length:	3.30 ft	Eq. external load:	0.00 tsf
Hammer energy ratio:	1.57		











F.S. color scheme

- Almost certain it will liquefy
- Very likely to liquefy
- Liquefaction and no liq. are equally likely
- Unlike to liquefy
- Almost certain it will not liquefy

LPI color scheme

- Very high risk
- High risk
- Low risk

:: Overall Liquefaction Assessment Analysis Plots ::

SPT BASED LIQUEFACTION ANALYSIS REPORT

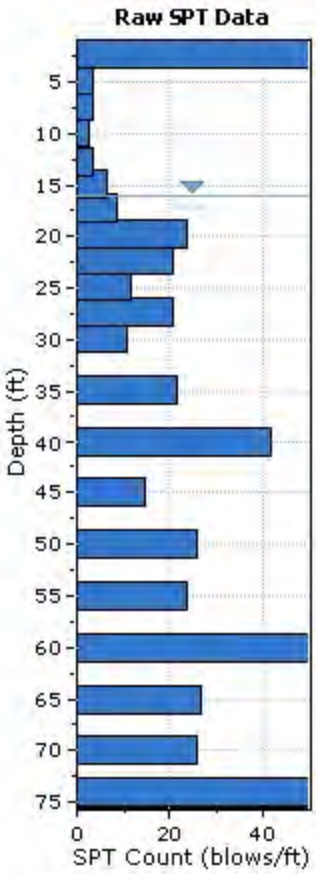
Project title : I-270 Bridge over COR

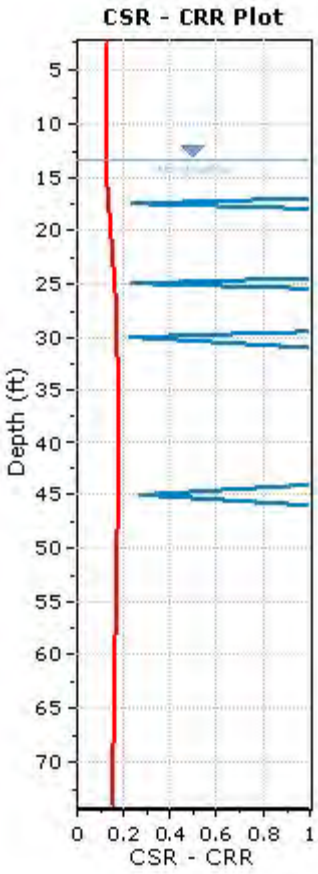
SPT Name: BB-32

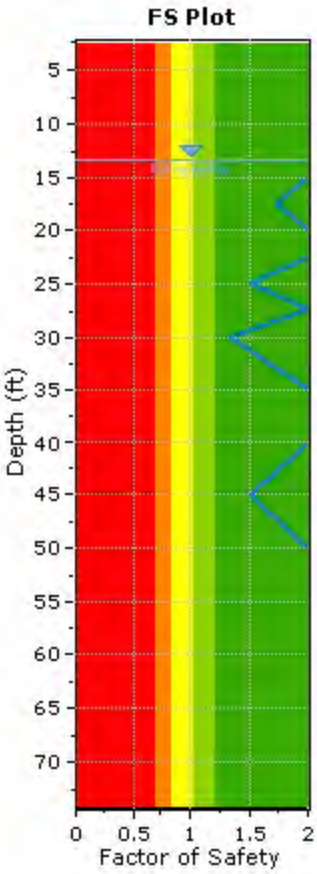
Location : Madison County, Illinois

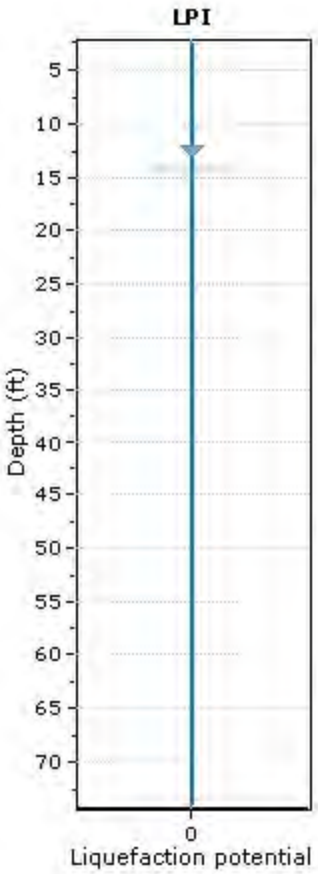
:: Input parameters and analysis properties ::

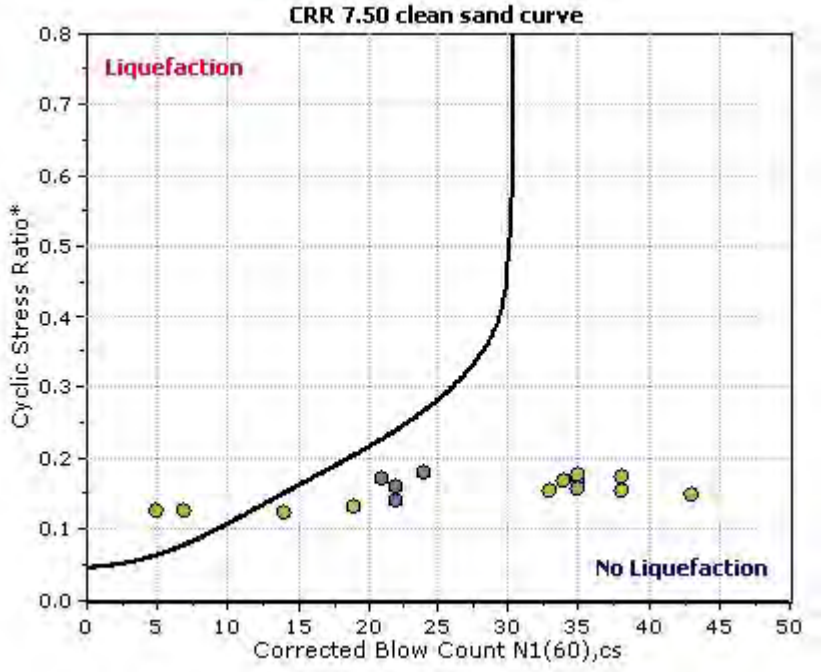
Analysis method:	NCEER 1998	G.W.T. (in-situ):	16.00 ft
Fines correction method:	NCEER 1998	G.W.T. (earthq.):	13.40 ft
Sampling method:	Standard Sampler	Earthquake magnitude M_w:	5.30 ft
Borehole diameter:	65mm to 115mm	Peak ground acceleration:	0.48 g
Rod length:	3.30 ft	Eq. external load:	0.00 tsf
Hammer energy ratio:	1.57		











F.S. color scheme

- Almost certain it will liquefy
- Very likely to liquefy
- Liquefaction and no liq. are equally likely
- Unlike to liquefy
- Almost certain it will not liquefy

LPI color scheme

- Very high risk
- High risk
- Low risk

:: Overall Liquefaction Assessment Analysis Plots ::

SPT BASED LIQUEFACTION ANALYSIS REPORT

Project title : I-270 Bridge over COR

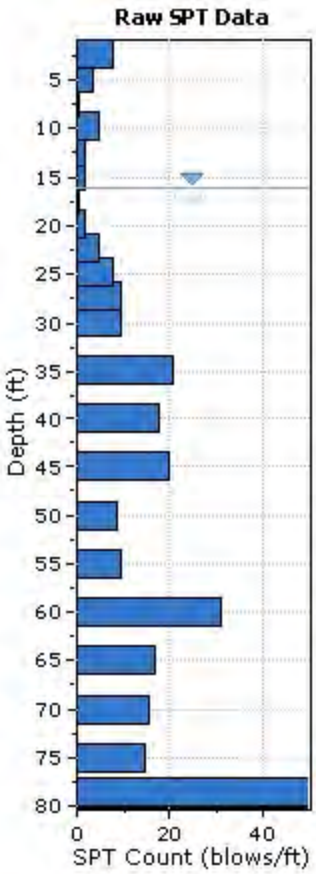
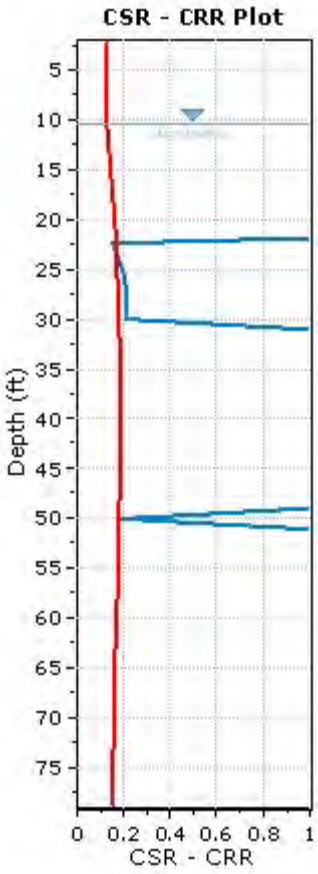
SPT Name: BB-40

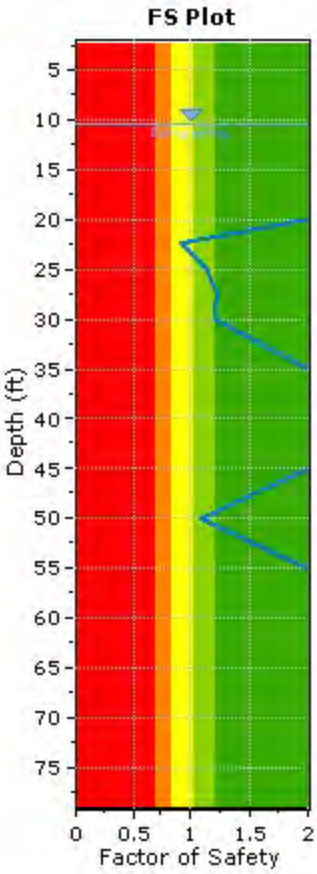
Location : Madison County, Illinois

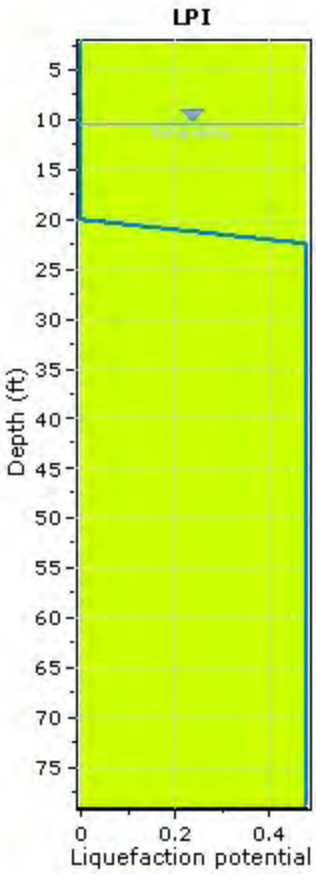
:: Input parameters and analysis properties ::

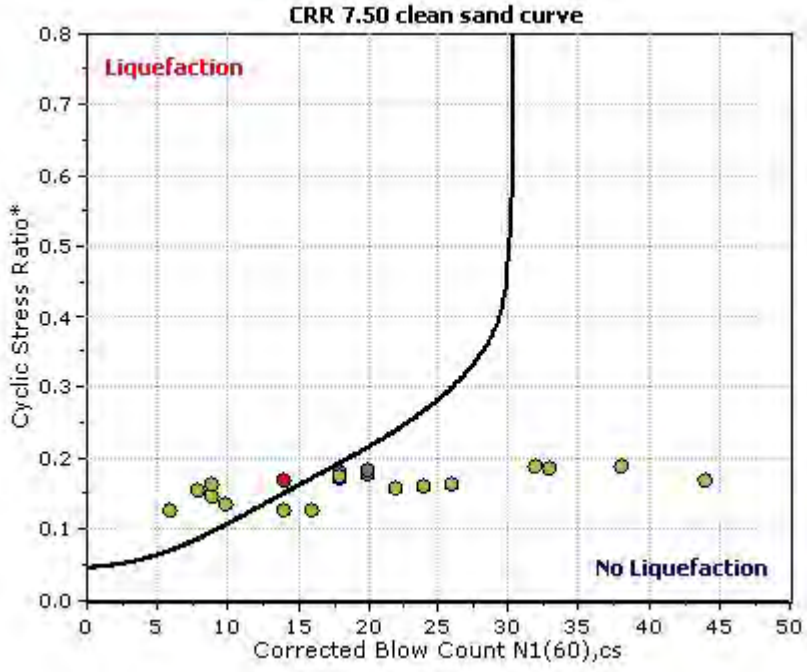
Analysis method:	NCEER 1998	G.W.T. (in-situ):	16.00 ft
Fines correction method:	NCEER 1998	G.W.T. (earthq.):	10.50 ft
Sampling method:	Standard Sampler	Earthquake magnitude M_w:	5.30 ft
Borehole diameter:	65mm to 115mm	Peak ground acceleration:	0.48 g
Rod length:	3.30 ft	Eq. external load:	0.00 tsf
Hammer energy ratio:	1.57		











F.S. color scheme

- Almost certain it will liquefy
- Very likely to liquefy
- Liquefaction and no liq. are equally likely
- Unlike to liquefy
- Almost certain it will not liquefy

LPI color scheme

- Very high risk
- High risk
- Low risk

:: Overall Liquefaction Assessment Analysis Plots ::

SPT BASED LIQUEFACTION ANALYSIS REPORT

Project title : I-270 Bridge over COR

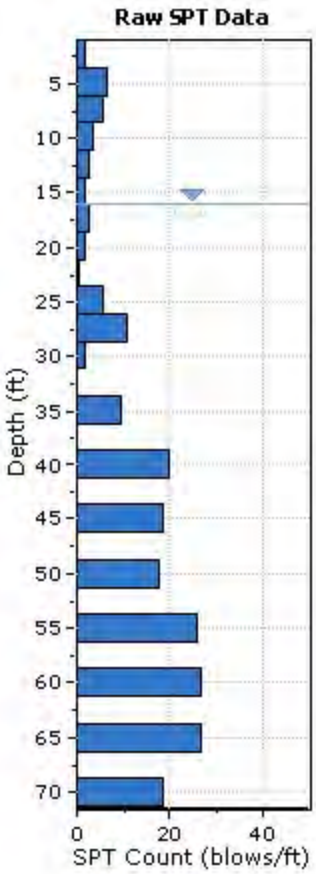
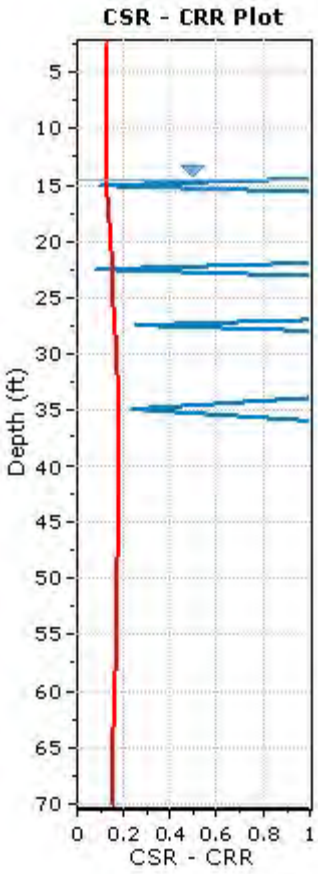
SPT Name: BB-45

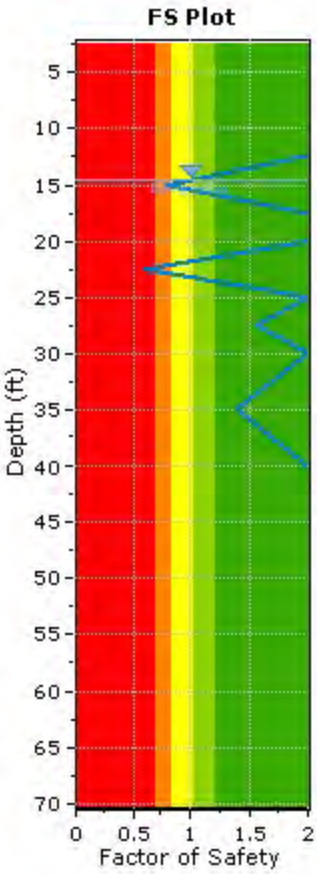
Location : Madison County, Illinois

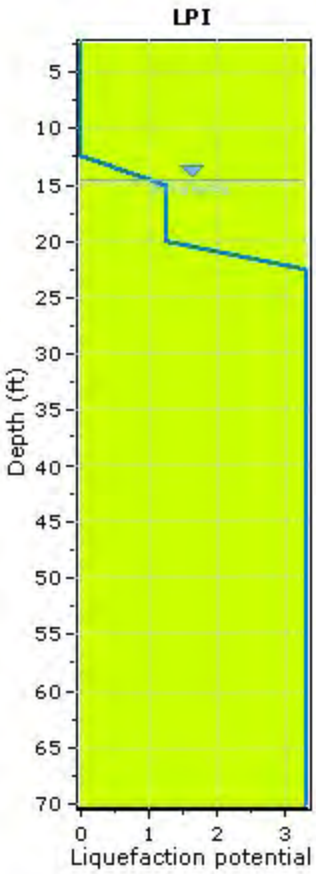
:: Input parameters and analysis properties ::

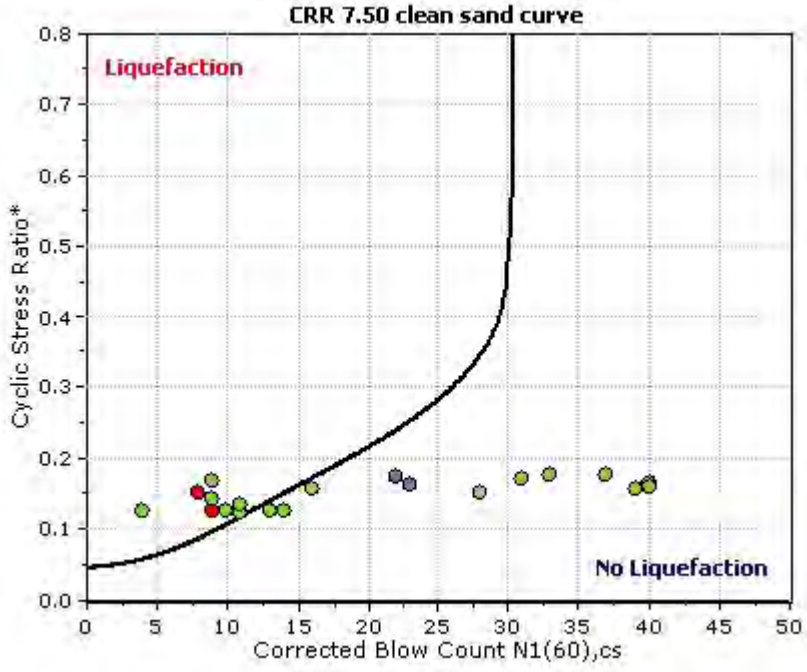
Analysis method:	NCEER 1998	G.W.T. (in-situ):	16.00 ft
Fines correction method:	NCEER 1998	G.W.T. (earthq.):	14.50 ft
Sampling method:	Standard Sampler	Earthquake magnitude M_w:	5.30 ft
Borehole diameter:	65mm to 115mm	Peak ground acceleration:	0.48 g
Rod length:	3.30 ft	Eq. external load:	0.00 tsf
Hammer energy ratio:	1.57		











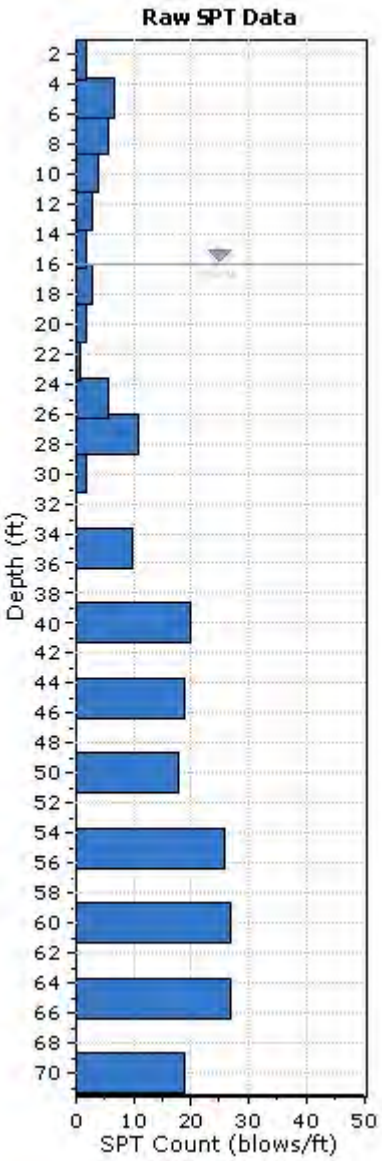
F.S. color scheme

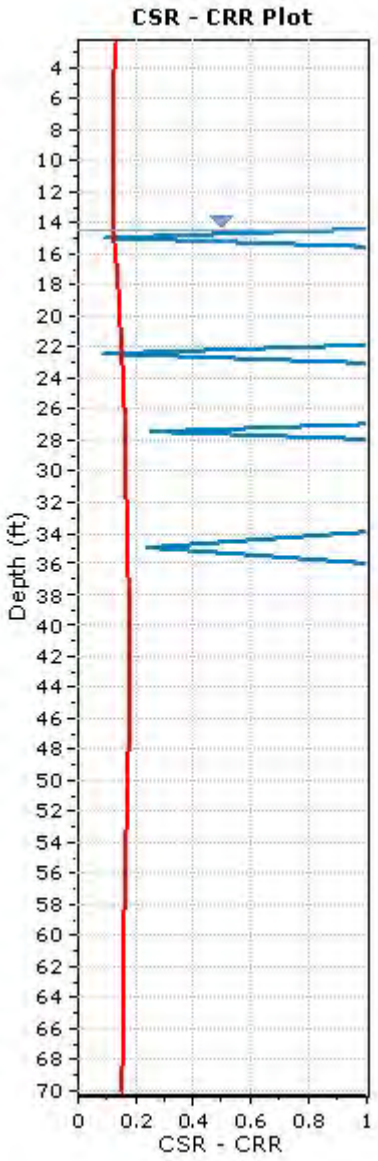
- Almost certain it will liquefy
- Very likely to liquefy
- Liquefaction and no liq. are equally likely
- Unlike to liquefy
- Almost certain it will not liquefy

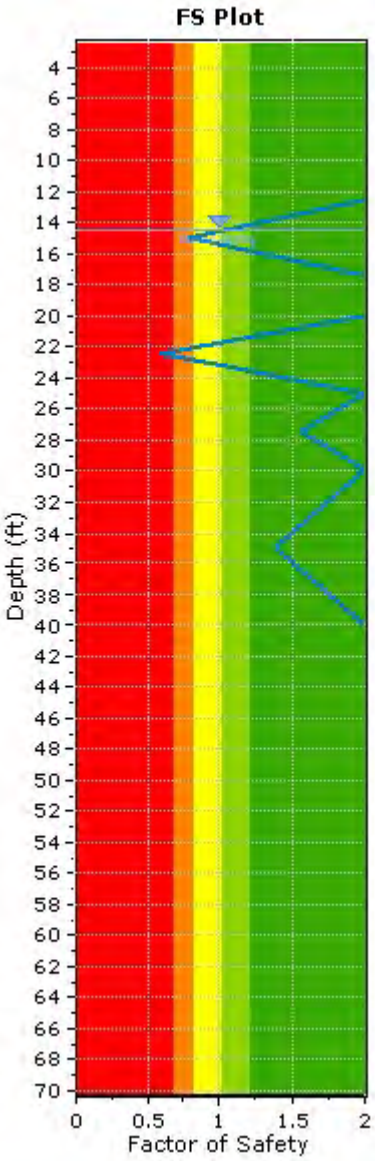
LPI color scheme

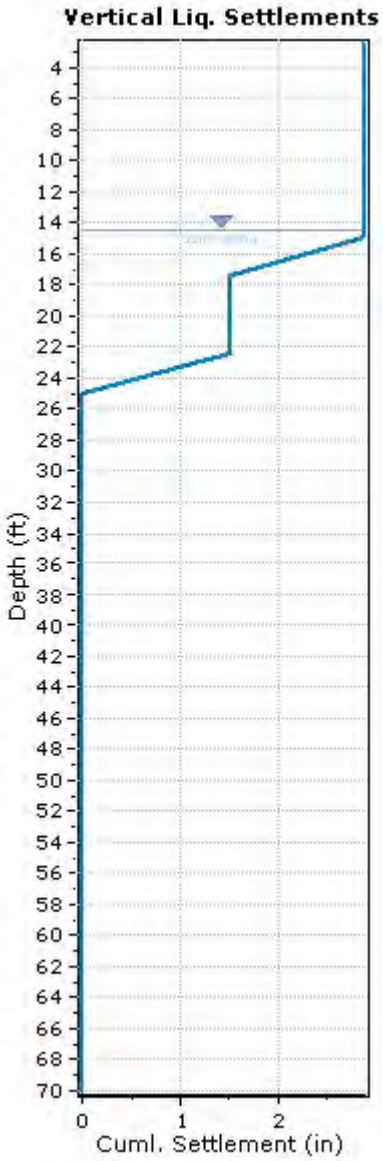
- Very high risk
- High risk
- Low risk

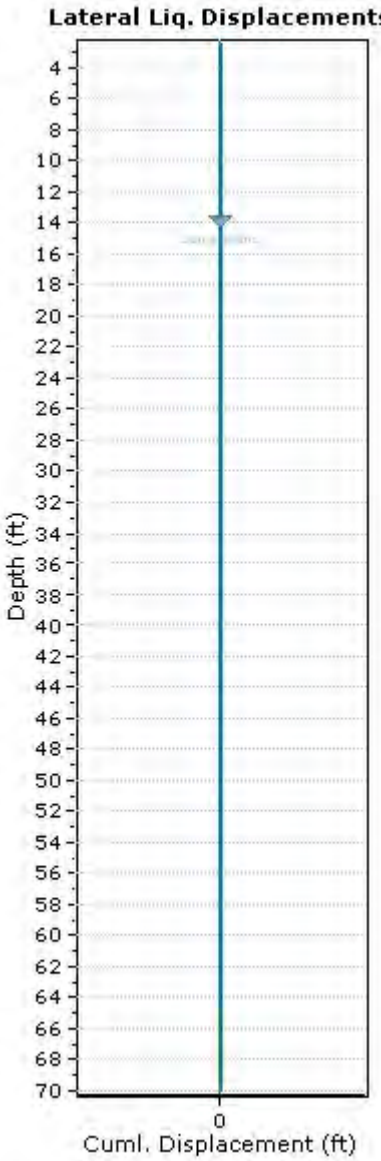
:: Overall Liquefaction Assessment Analysis Plots ::











SCI LIQUEFACTION ANALYSIS

Modified from I.D.O.T. Bureau of Bridges and Structures FOUNDATIONS AND GEOTECHNICAL UNIT — Modified 6/14/2013

REFERENCE BORING NUMBER ========== BB-46
ELEVATION OF BORING GROUND SURFACE ========== 414.50 FT.

SPT BASED LIQUEFACTION ANALYSIS REPORT

Project title : I-270 Bridge over COR

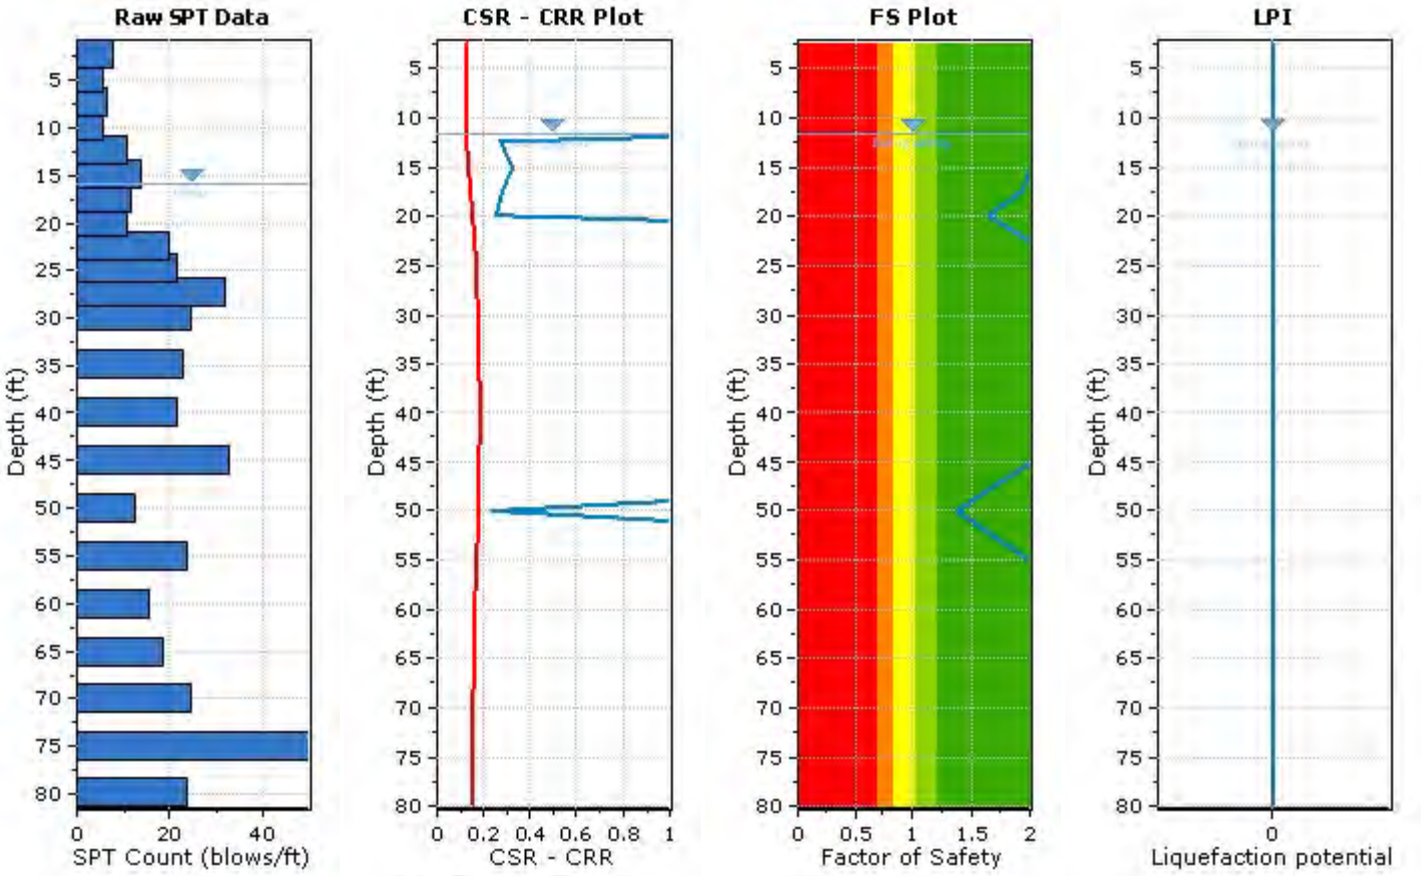
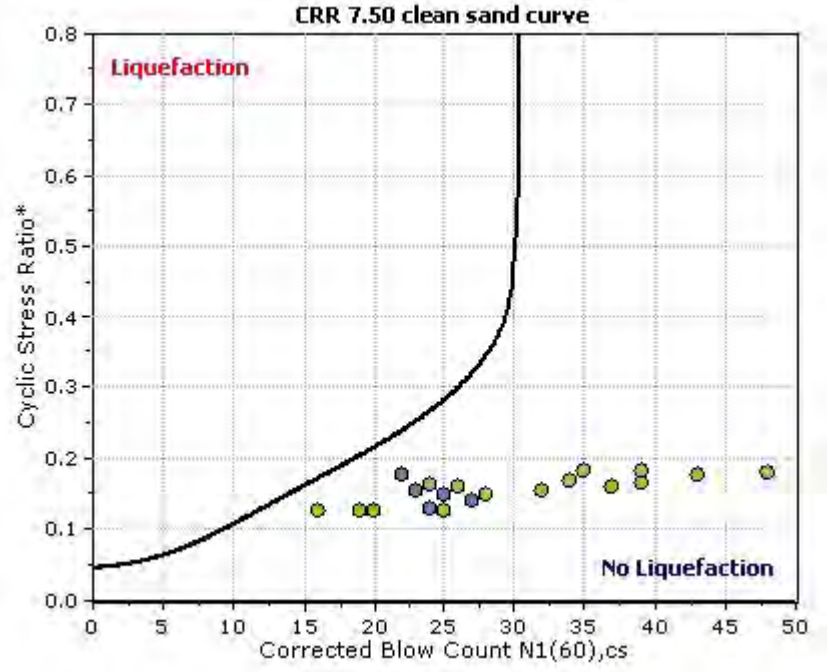
SPT Name: BB-48

Location : Madison County, Illinois

:: Input parameters and analysis properties ::

Analysis method:	NCEER 1998	G.W.T. (in-situ):	16.00 ft
Fines correction method:	NCEER 1998	G.W.T. (earthq.):	11.70 ft
Sampling method:	Standard Sampler	Earthquake magnitude M_w:	5.30 ft
Borehole diameter:	65mm to 115mm	Peak ground acceleration:	0.48 g
Rod length:	3.30 ft	Eq. external load:	0.00 tsf
Hammer energy ratio:	1.57		





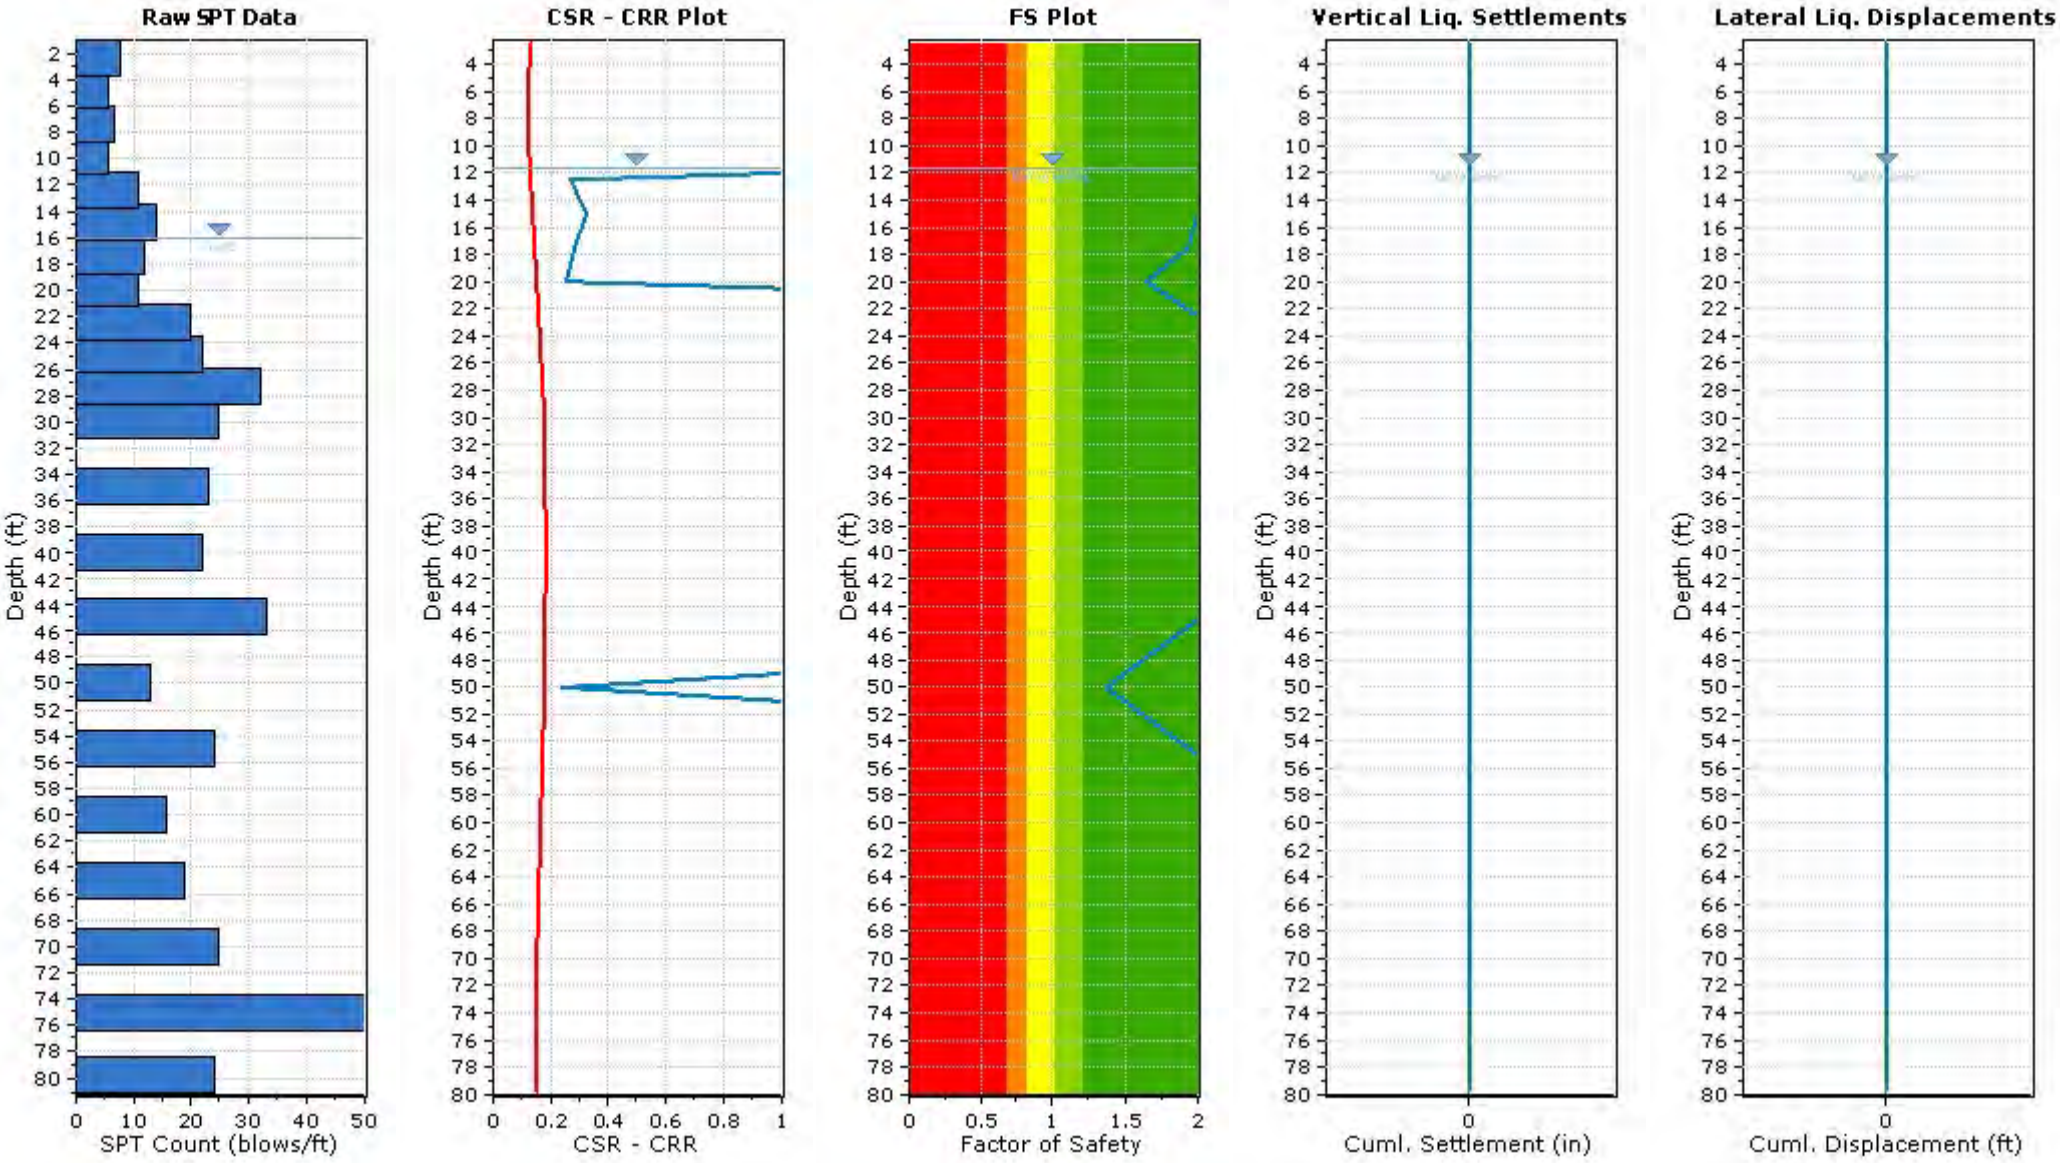
F.S. color scheme

- Almost certain it will liquefy
- Very likely to liquefy
- Liquefaction and no liq. are equally likely
- Unlike to liquefy
- Almost certain it will not liquefy

LPI color scheme

- Very high risk
- High risk
- Low risk

:: Overall Liquefaction Assessment Analysis Plots ::



SCI LIQUEFACTION ANALYSIS

Modified from I.D.O.T. Bureau of Bridges and Structures FOUNDATIONS AND GEOTECHNICAL UNIT — Modified 6/14/2013

REFERENCE BORING NUMBER ========== BB-49
ELEVATION OF BORING GROUND SURFACE ========== 426.90 FT.
DEPTH TO GROUNDWATER - DURING DRILLING ========== 23.50 FT. (Below Boring Ground Surface)
DEPTH TO GROUNDWATER - DURING EARTHQUAKE ========== 20.20 FT. (Below Finished Grade Cut or Fill Surface)
PEAK HORIZ. GROUND SURFACE ACCELERATION COEFFICIENT (As) ========== 0.487
EARTHQUAKE MOMENT MAGNITUDE ========== 5.3
FINISHED GRADE FILL OR CUT FROM BORING SURFACE ========== 0.00 FT.
HAMMER EFFICIENCY========== 86 %
BOREHOLE DIAMETER========== 6 IN.
SAMPLING METHOD========== Sampler w/out Liners

SPT BASED LIQUEFACTION ANALYSIS REPORT

Project title : I-270 Bridge over COR

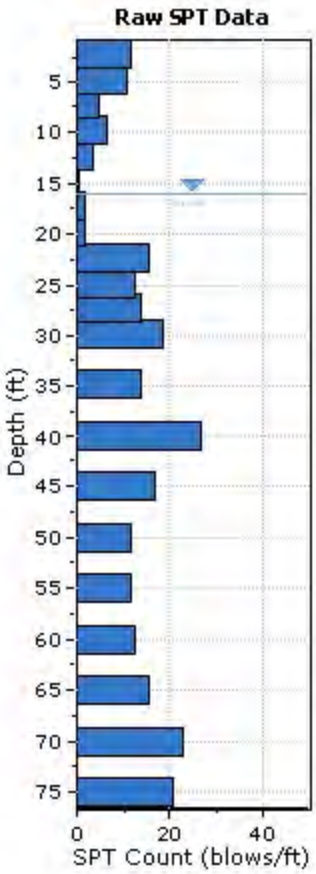
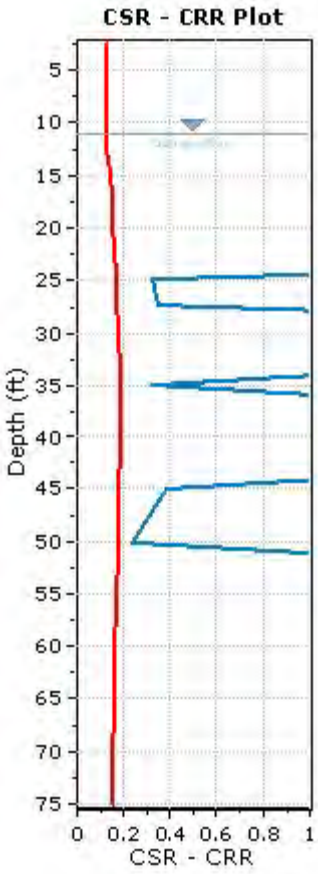
SPT Name: BB-54

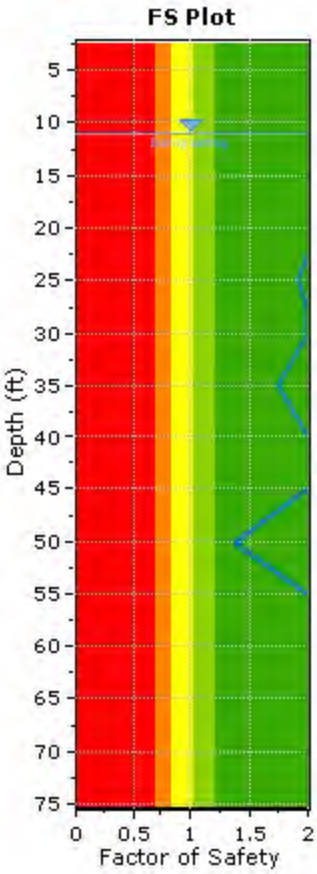
Location : Madison County, Illinois

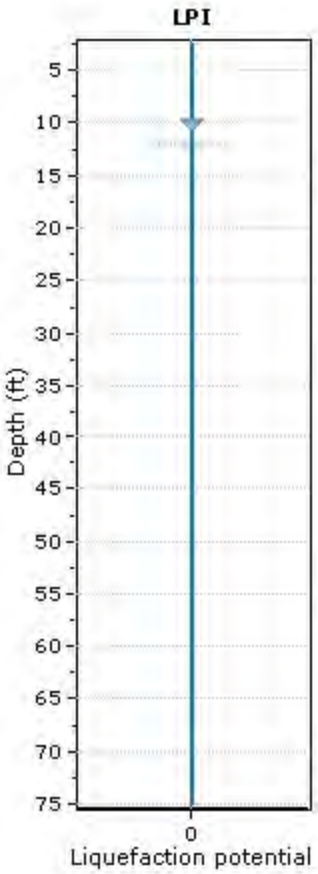
:: Input parameters and analysis properties ::

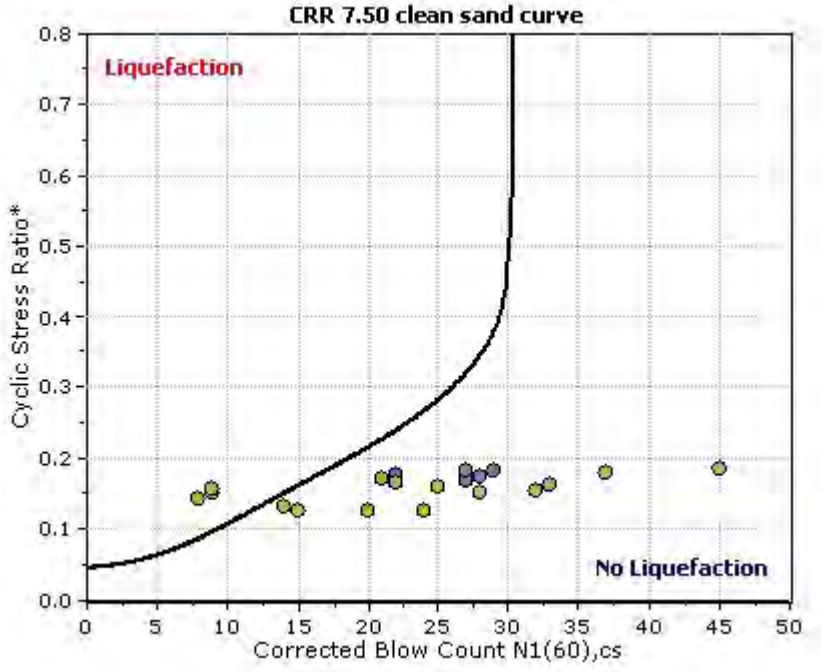
Analysis method:	NCEER 1998	G.W.T. (in-situ):	16.00 ft
Fines correction method:	NCEER 1998	G.W.T. (earthq.):	11.10 ft
Sampling method:	Standard Sampler	Earthquake magnitude M_w:	5.30 ft
Borehole diameter:	65mm to 115mm	Peak ground acceleration:	0.48 g
Rod length:	3.30 ft	Eq. external load:	0.00 tsf
Hammer energy ratio:	1.57		











F.S. color scheme

- Almost certain it will liquefy
- Very likely to liquefy
- Liquefaction and no liq. are equally likely
- Unlike to liquefy
- Almost certain it will not liquefy

LPI color scheme

- Very high risk
- High risk
- Low risk

:: Overall Liquefaction Assessment Analysis Plots ::

SPT BASED LIQUEFACTION ANALYSIS REPORT

Project title : I-270 Bridge over COR

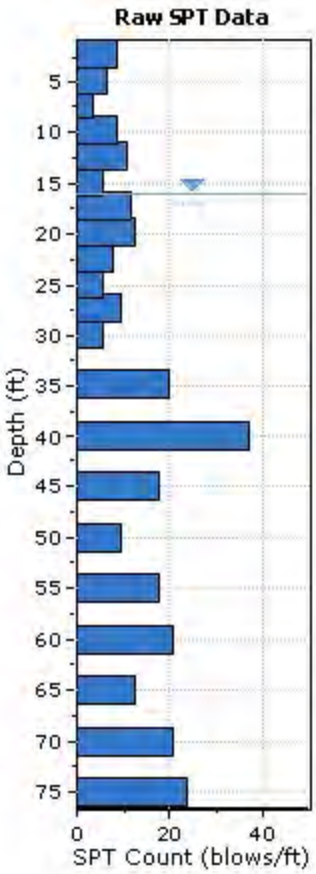
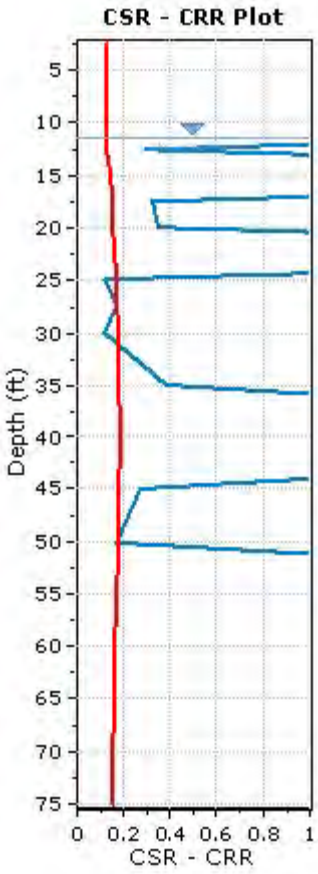
SPT Name: BB-56

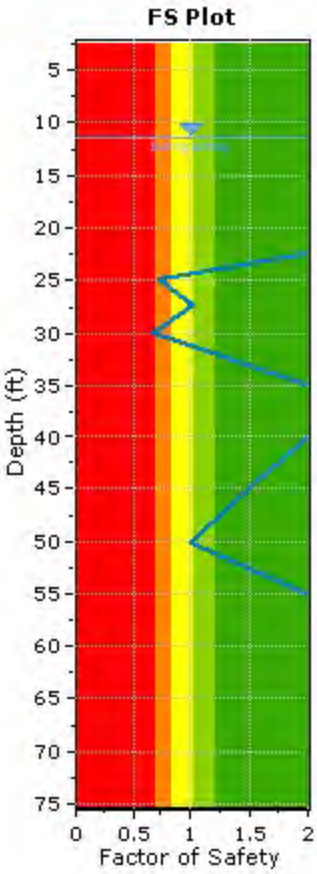
Location : Madison County, Illinois

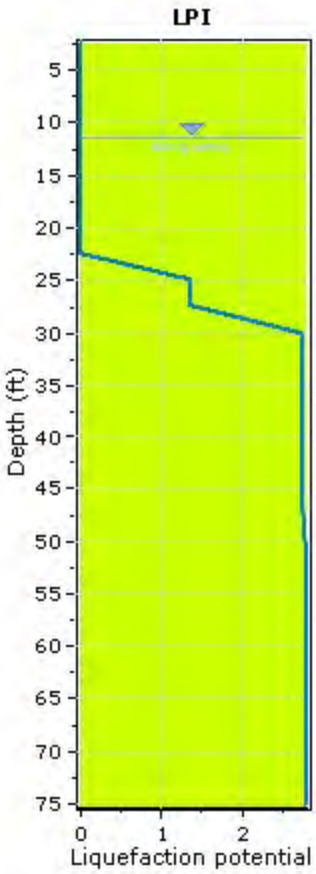
:: Input parameters and analysis properties ::

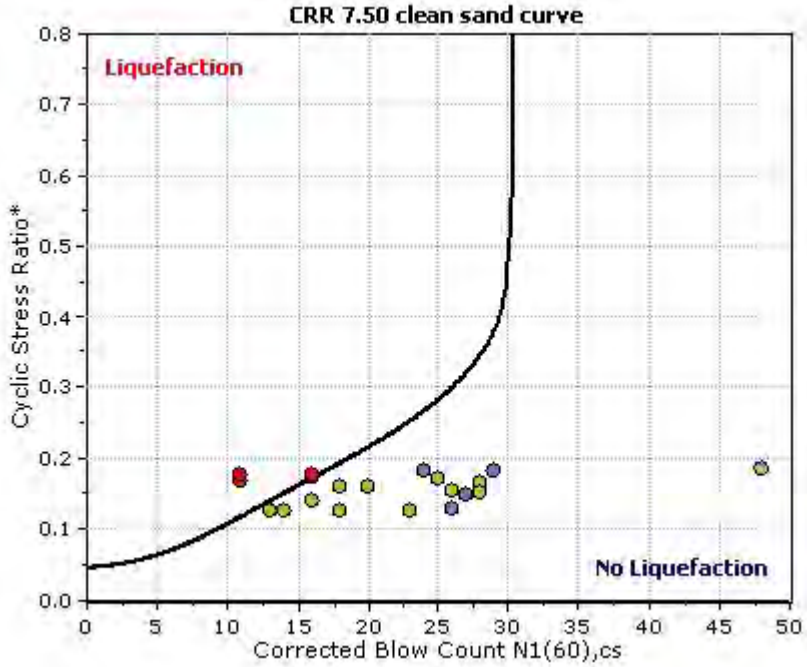
Analysis method:	NCEER 1998	G.W.T. (in-situ):	16.00 ft
Fines correction method:	NCEER 1998	G.W.T. (earthq.):	11.40 ft
Sampling method:	Standard Sampler	Earthquake magnitude M_w:	5.30 ft
Borehole diameter:	65mm to 115mm	Peak ground acceleration:	0.48 g
Rod length:	3.30 ft	Eq. external load:	0.00 tsf
Hammer energy ratio:	1.57		











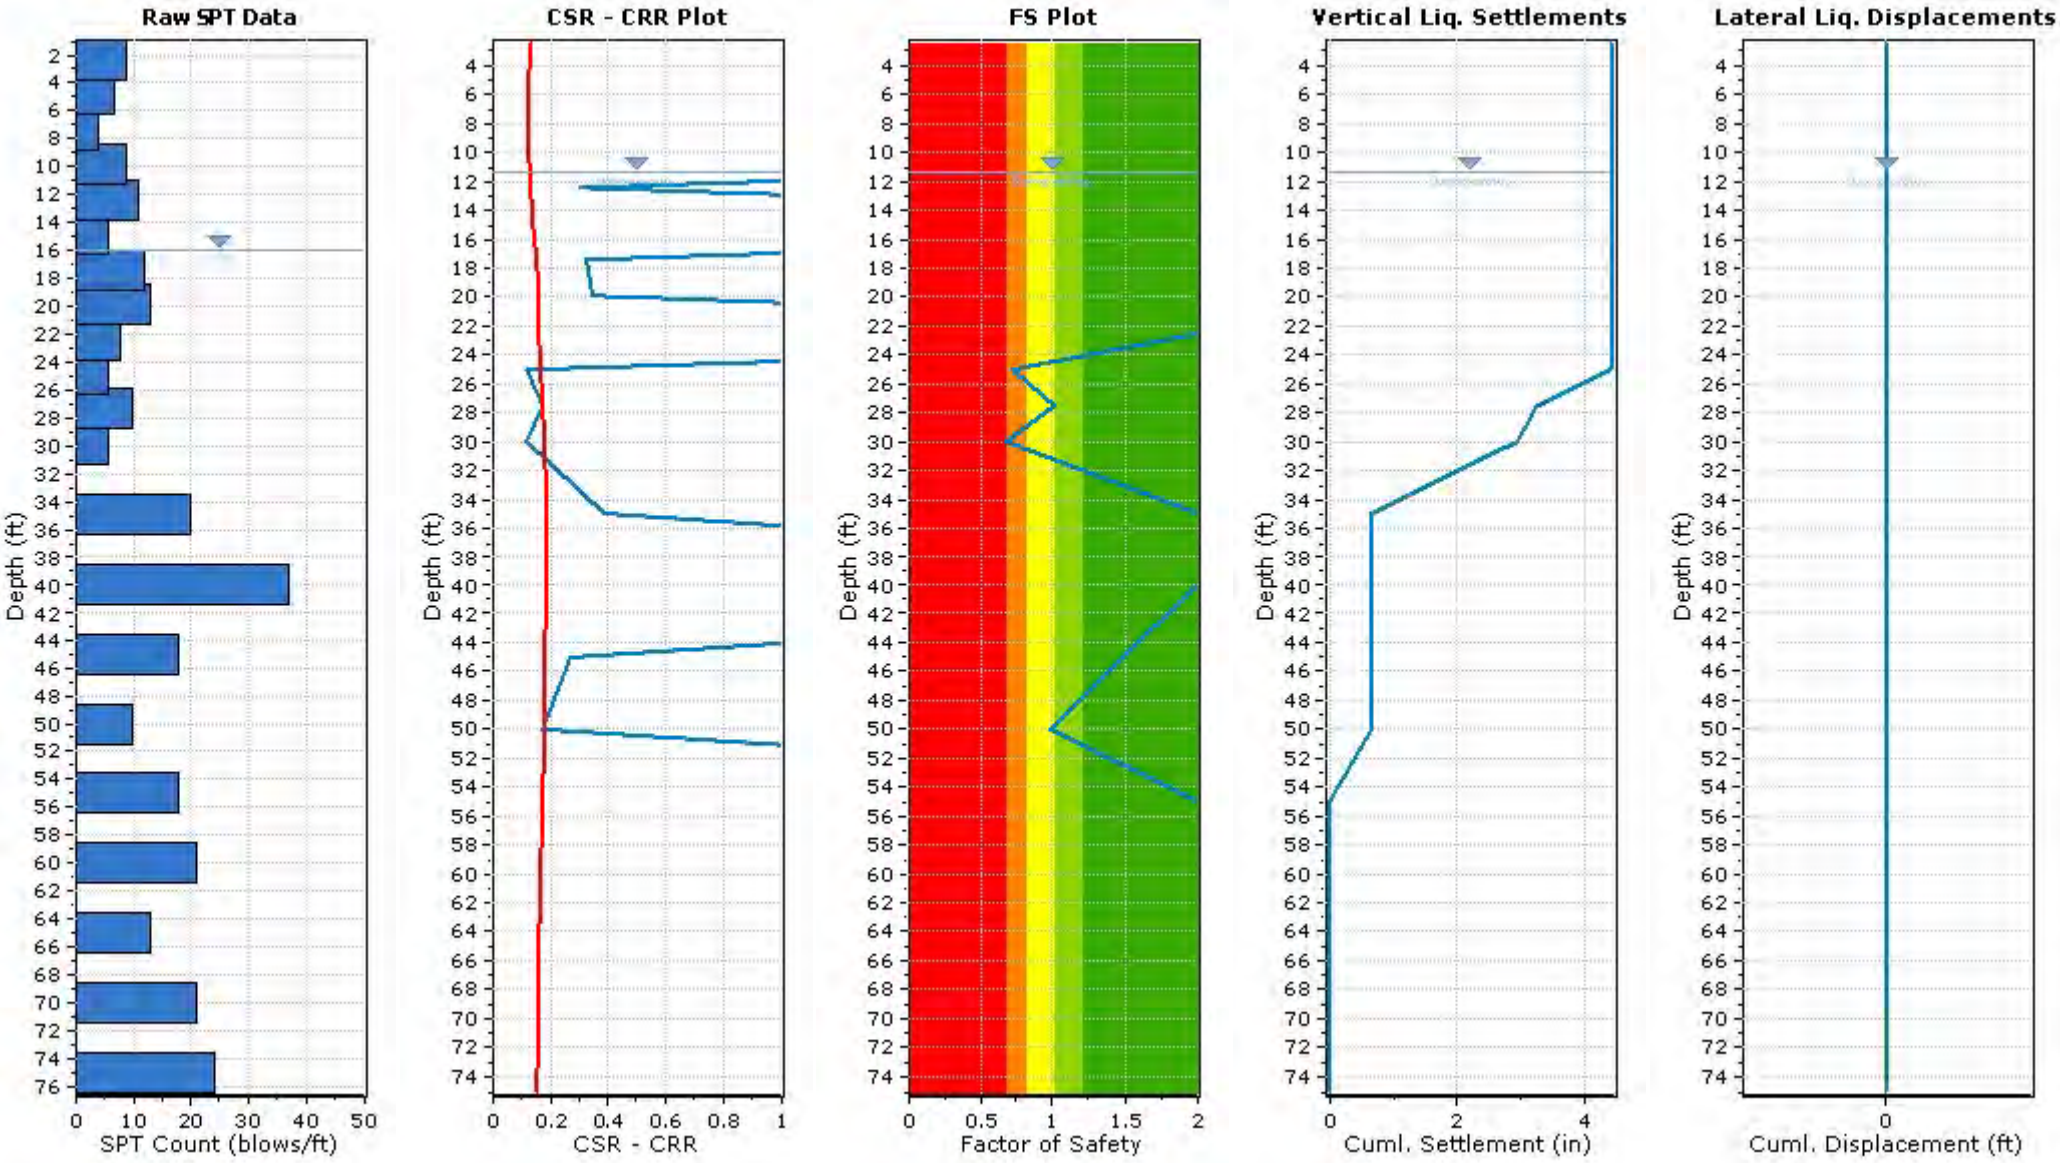
F.S. color scheme

- Almost certain it will liquefy
- Very likely to liquefy
- Liquefaction and no liq. are equally likely
- Unlike to liquefy
- Almost certain it will not liquefy

LPI color scheme

- Very high risk
- High risk
- Low risk

:: Overall Liquefaction Assessment Analysis Plots ::



SCI LIQUEFACTION ANALYSIS

Modified from I.D.O.T. Bureau of Bridges and Structures FOUNDATIONS AND GEOTECHNICAL UNIT — Modified 6/14/2013

REFERENCE BORING NUMBER ========== BB-58
ELEVATION OF BORING GROUND SURFACE ========== 413.20 FT.
DEPTH TO GROUNDWATER - DURING DRILLING ========== 6.50 FT. (Below Boring Ground Surface)
DEPTH TO GROUNDWATER - DURING EARTHQUAKE ========== 6.50 FT. (Below Finished Grade Cut or Fill Surface)
PEAK HORIZ. GROUND SURFACE ACCELERATION COEFFICIENT (As) ========== 0.487
EARTHQUAKE MOMENT MAGNITUDE ========== 5.3
FINISHED GRADE FILL OR CUT FROM BORING SURFACE ========== 0.00 FT.
HAMMER EFFICIENCY========== 86 %
BOREHOLE DIAMETER========== 6 IN.
SAMPLING METHOD========== Sampler w/out Liners

EQ MAGNITUDE SCALING FACTOR
(MSF) = **2.169**

AVG. SHEAR WAVE VELOCITY (top 40')
$\bar{V}_{s,40'}$ = **665** FT./SEC.

PGA CALCULATOR
Earthquake Moment Magnitude = 5.3
Source-To-Site Distance, R (km) = 10

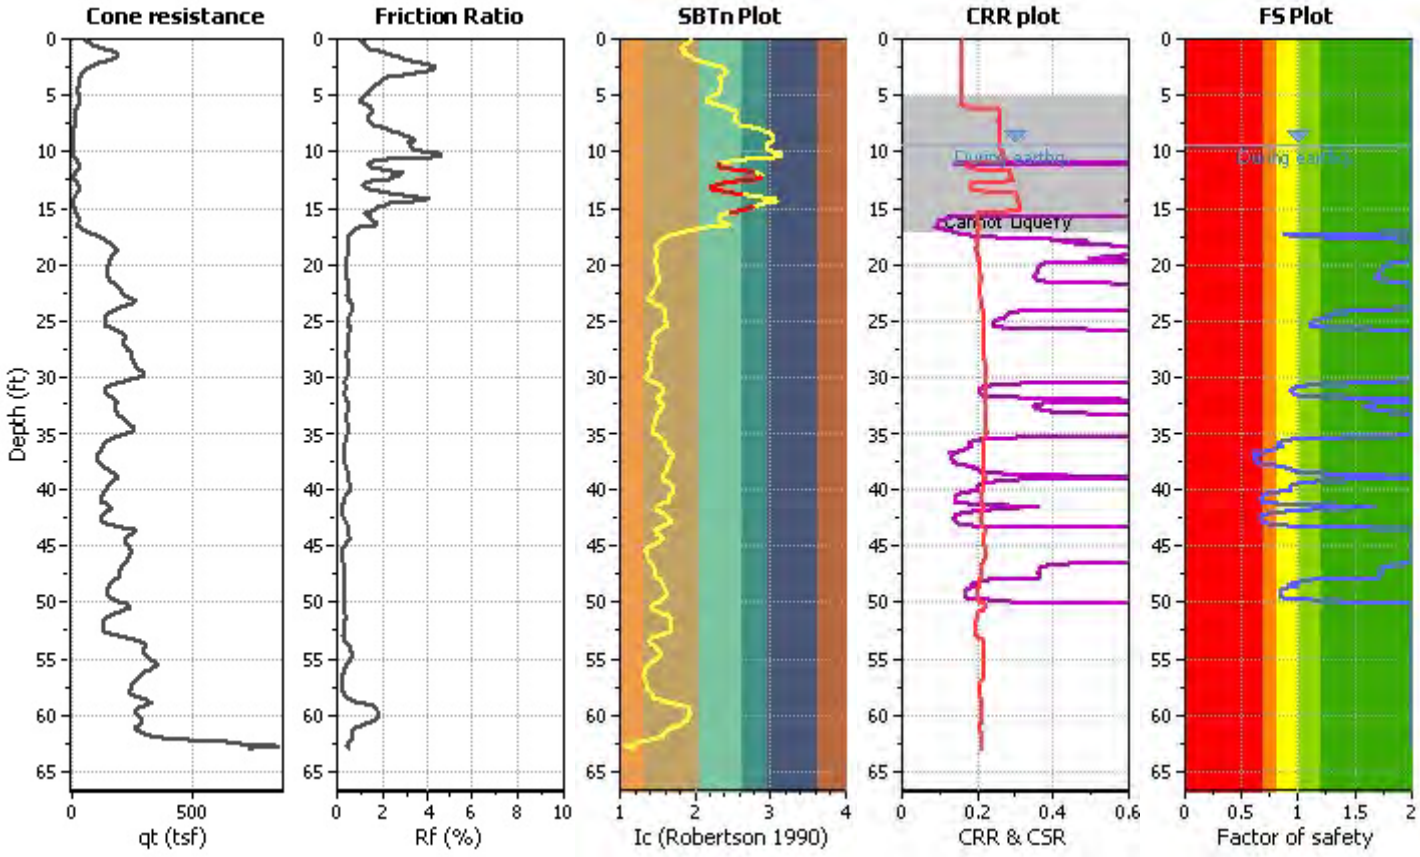
LIQUEFACTION ANALYSIS REPORT

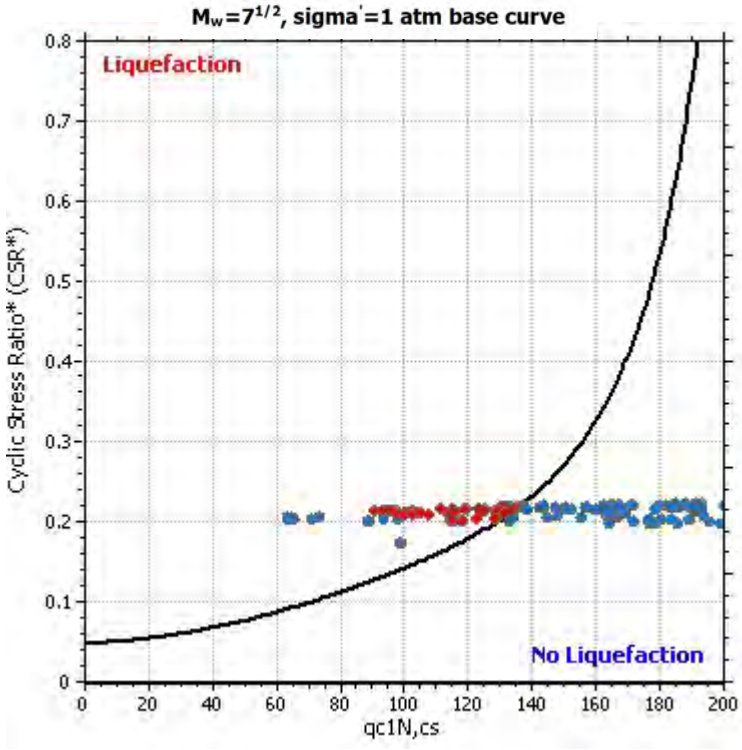
Project title : PTB 185-20 I270 Bridge: 2017-3167.10 **Location : Madison County, IL**

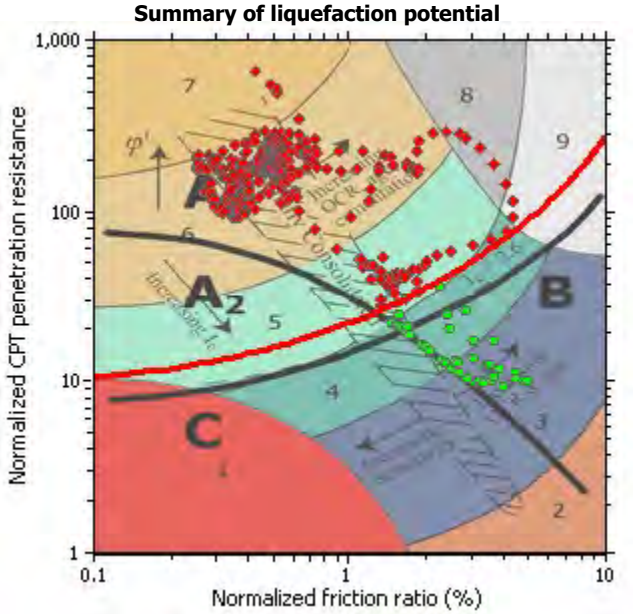
CPT file : C-108

Input parameters and analysis data

Analysis method:	I&B (2008)	G.W.T. (in-situ):	5.00 ft	Use fill:	No	Clay like behavior applied:	Sand & Clay
Fines correction method:	R&W (1998)	G.W.T. (earthq.):	9.40 ft	Fill height:	N/A	Limit depth applied:	Yes
Points to test:	Based on Ic value	Average results interval:	5	Fill weight:	N/A	Limit depth:	50.00 ft
Earthquake magnitude M_w:	5.30	Ic cut-off value:	2.45	Trans. detect. applied:	Yes	MSF method:	Method
Peak ground acceleration:	0.48	Unit weight calculation:	Based on SBT	K_σ applied:	Yes		

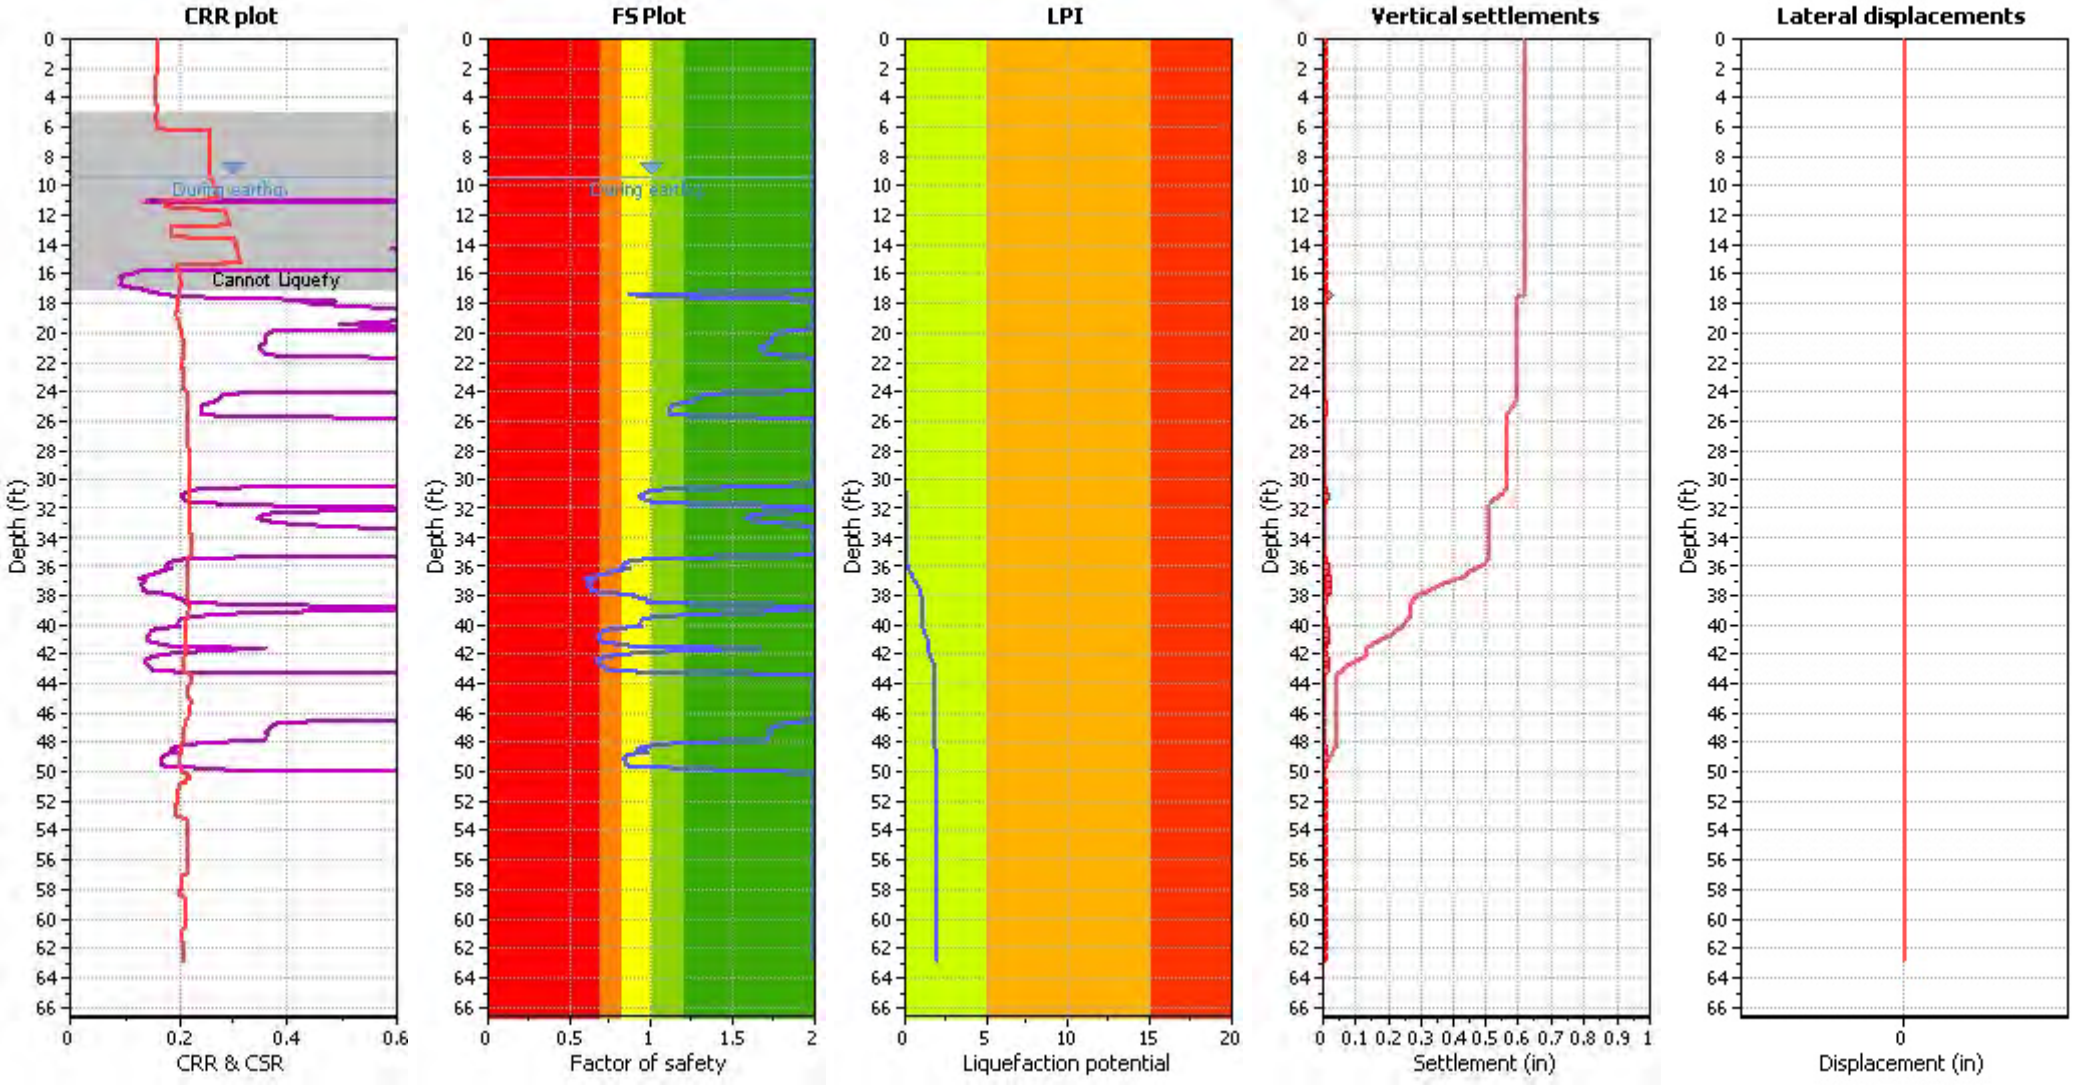






Zone A_1: Cyclic liquefaction likely depending on size and duration of cyclic loading
Zone A_2: Cyclic liquefaction and strength loss likely depending on loading and ground geometry
Zone B: Liquefaction and post-earthquake strength loss unlikely, check cyclic softening
Zone C: Cyclic liquefaction and strength loss possible depending on soil plasticity, brittleness/sensitivity, strain to peak undrained strength and ground geometry

Liquefaction analysis overall plot



Input parameters and analysis data

Analysis method:	I&B (2008)	Depth to GWT (erthq.):	9.40 ft	Fill weight:	N/A

APPENDIX C
Embankment Settlement Calculations

COHESIVE SOIL SETTLEMENT ESTIMATE

Illinois Department of Transportation

LOCATION AND BORING USED ========== BB-01
TYPE OF SURCHARGE ========== 2 (1=2:1 bridge cone, 2=continuous embank., 3=rectangular surch.)
DEPTH TO WATER TABLE (below top of existing embankment) == 36 FT

NEW EMBANKMENT:
- NEW EMBANKMENT FILL UNIT WEIGHT ========== 120 PCF
- NEW EMBANKMENT FILL HEIGHT ========== 28 FT
- PROPOSED WIDTH AT TOP ========== 80 FT
- PROPOSED WIDTH AT BOTTOM ========== 260 FT (which is a 3.2:1 slope)

EXISTING EMBANKMENT (IF ANY):
- EXISTING EMBANKMENT UNIT WEIGHT ========== 120 PCF
- EXISTING EMBANKMENT HEIGHT ========== 18 FT
- EXISTING WIDTH AT TOP ========== 80 FT
- EXISTING WIDTH AT BASE ========== 185 FT (which is a 2.9:1 slope)

ASSUMPTIONS:
- Soil Deposit is Normally Consolidated
- Cohesive Layers are Saturated
- Soils have a Low Sensitivity
- Liquid Limit (LL)=Moist. Content (MC%)
- Initial Void Ratio (Eo)=2.7*(MC%)/100
- Comp. Index (Cc)=0.009*(LL-10)
- Neglecting Granular & Secondary Settlem't

LAYER THICK (FT)	*TOTAL UNIT WT. (PCF)*	*UNCONF. COMP. STRENGTH (Qu) (TSF)*	*MOIST. CONTENT (%)*	*EXISTING PRESSURE (KSF)*	*PRESSURE INCREASE (KSF)*	*INITIAL VOID RATIO*	*COMPRESSION INDEX (Cc)*	*Qu CORRECTION FACTOR*	*LAYER SETTLEMENT (IN.)*

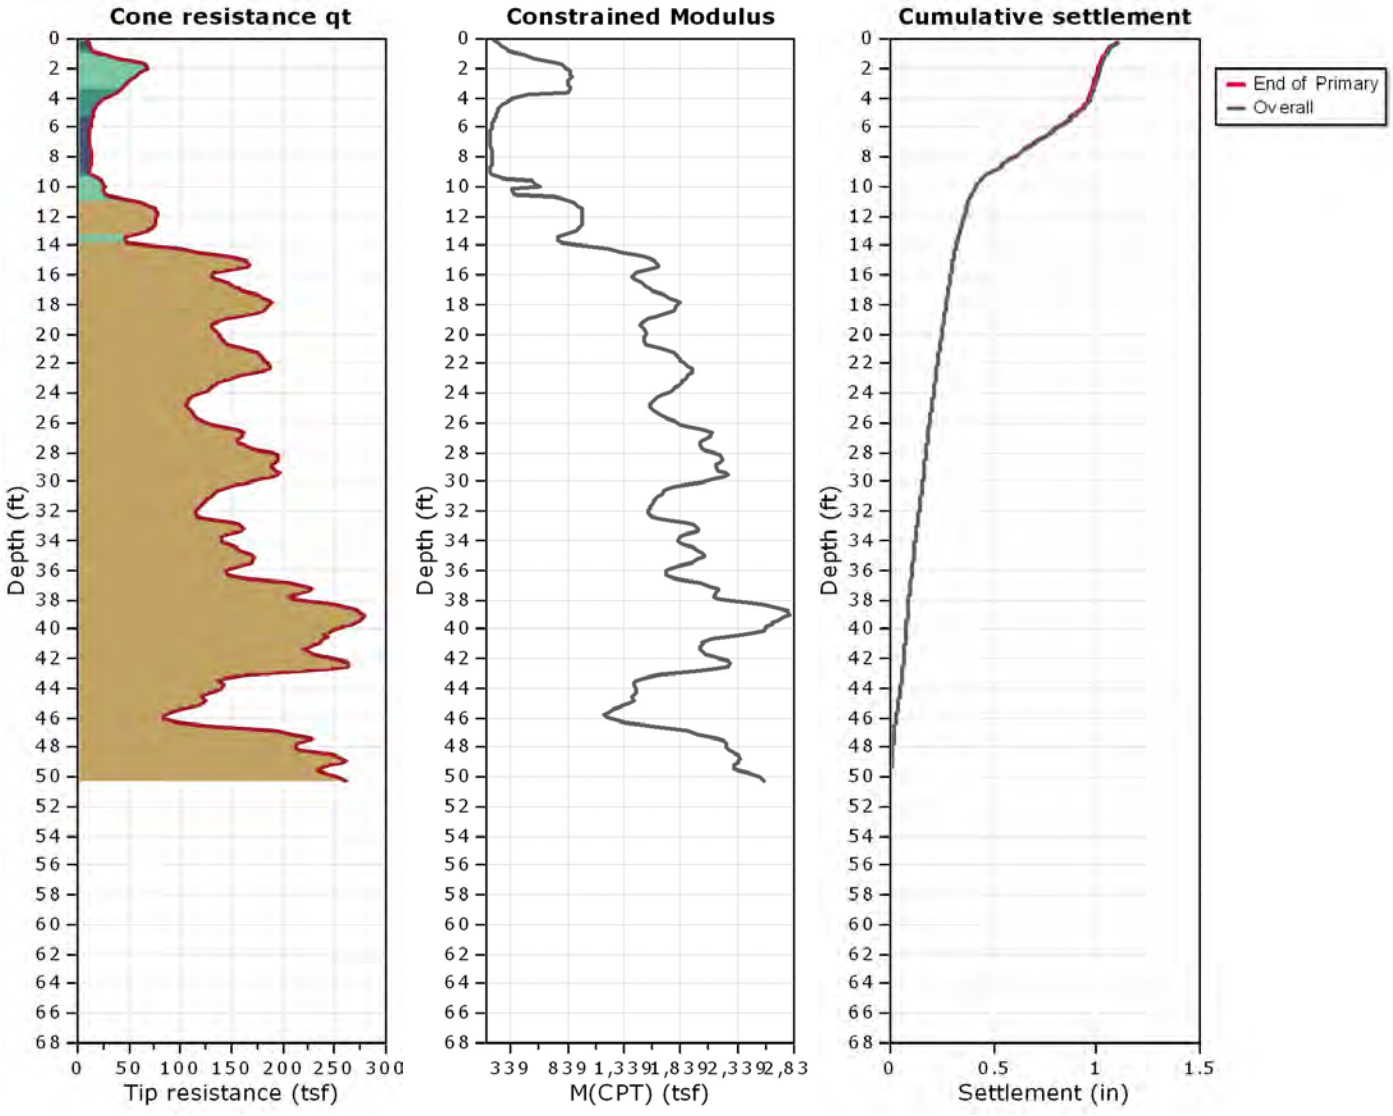
CPT: C-111
Total depth: 50.20 ft, Date: 9/21/2018
Surface Elevation: 419.00 ft
Coords: X:0.00, Y:0.00
Cone Type: Uknown
Cone Operator: Uknown

Project: **PTB 185-20 I270 Bridge: 2017-3167.10**
Location: **Granite City, IL**

Settlements calculation according to theory of elasticity*



Calculation properties

Footing type: Rectangular
Footing width: 80.00 (ft)
L/B: 10.0
Footing pressure: 1.50 (tsf)
Embedment depth: 0.00 (ft)
Footing is rigid: No
Remove excavation load: No
Apply 20% rule: No
Calculate secondary settlements: Yes
Time period for primary consolidation: 6 months
Time period for second. settlements: 60 months

* Primary settlements calculation is performed according to the following formula:

$$S = \sum \frac{\Delta \sigma_v}{M_{CPT}} \Delta z$$

* Secondary (creep) settlements calculation is performed according to the following formula:

$$S = C_a \cdot \Delta z \cdot \log(t)$$

Pile Capacity Tables

Illinois Department of Transportation

IDOT STATIC METHOD OF ESTIMATING PILE LENGTH

SUBSTRUCTURE========== West Abutment
REFERENCE BORING ========== BB-01
LRFD or ASD or SEISMIC ========== LRFD
PILE CUTOFF ELEV. ========== 443.40 ft
GROUND SURFACE ELEV. AGAINST PILE DURING DRIVING = 441.40 ft
GEOTECHNICAL LOSS TYPE (None, Scour, Liquef., DD) ====== None
BOTTOM ELEV. OF SCOUR, LIQUEF., or DD ========== 431.00 ft
TOP ELEV. OF LIQUEF. (so layers above apply DD) ========== 441.40 ft

TOTAL FACTORED SUBSTRUCTURE LOAD ========== 3000 kips
TOTAL LENGTH OF SUBSTRUCTURE (along skew)========== 66.00 ft
NUMBER OF ROWS OF PILES PER SUBSTRUCTURE ======= 2
Approx. Factored Loading Applied per pile at 8 ft. Cts ========== 181.82 KIPS
Approx. Factored Loading Applied per pile at 3 ft. Cts ========== 68.18 KIPS

MAX. REQUIRED BEARING & RESISTANCE for Selected Pile, Soil Profile, & Losses

Maximum Nominal Req'd Bearing of Pile	Maximum Nominal Req.d Bearing of Boring	Maximum Factored Resistance Available in Boring	Maximum Pile Driveable Length in Boring
810 KIPS	**810** KIPS	**445** KIPS	**57** FT.

PILE TYPE AND SIZE ========== Steel HP 14 X 102
Plugged Pile Perimeter========== 4.800 FT. Unplugged Pile Perimeter========== 7.058 FT.
Plugged Pile End Bearing Area========== 1.439 SQFT. Unplugged Pile End Bearing Area========= 0.208 SQFT.

Illinois Department of Transportation

IDOT STATIC METHOD OF ESTIMATING PILE LENGTH

SUBSTRUCTURE========== East Abutment
REFERENCE BORING ========== BB-49
LRFD or ASD or SEISMIC ========== SEISMIC
PILE CUTOFF ELEV. ========== 442.20 ft
GROUND SURFACE ELEV. AGAINST PILE DURING DRIVING = 438.20 ft
GEOTECHNICAL LOSS TYPE (None, Scour, Liquef., DD) ====== None
BOTTOM ELEV. OF SCOUR, LIQUEF., or DD ========== ft
TOP ELEV. OF LIQUEF. (so layers above apply DD) ========== ft

TOTAL SEISMIC SUBSTRUCTURE LOAD ========== 3000 kips
TOTAL LENGTH OF SUBSTRUCTURE (along skew)========== 66.00 ft
NUMBER OF ROWS OF PILES PER SUBSTRUCTURE ======= 2
Approx. Seismic Loading Applied per pile spaced at 8 ft. Cts ======= 181.82 KIPS
Approx. Seismic Loading Applied per pile spaced at 3 ft. Cts ======= 68.18 KIPS

MAX. REQUIRED BEARING & RESISTANCE for Selected Pile, Soil Profile, & Losses

Maximum Nominal Req'd Bearing of Pile	Maximum Nominal Req.d Bearing of Boring	Maximum Seismic Resistance Available in Boring	Maximum Pile Driveable Length in Boring
929 KIPS	**929** KIPS	**929** KIPS	**112** FT.

PILE TYPE AND SIZE ========== Steel HP 14 X 117
Plugged Pile Perimeter========== 4.850 FT. Unplugged Pile Perimeter========== 7.117 FT.
Plugged Pile End Bearing Area========== 1.469 SQFT. Unplugged Pile End Bearing Area========== 0.239 SQFT.

BOT. OF LAYER ELEV. (FT.)	LAYER THICK. (FT.)	UNCONF. COMPR. STRENGTH (TSF.)	S.P.T. N VALUE (BLOWS)	GRANULAR OR ROCK LAYER DESCRIPTION	ULTIMATE PLUGGED SIDE RESIST. (KIPS)	ULTIMATE PLUGGED END BRG. APPENDIX G
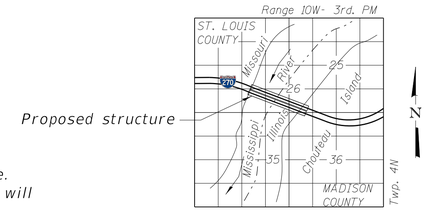
TSL

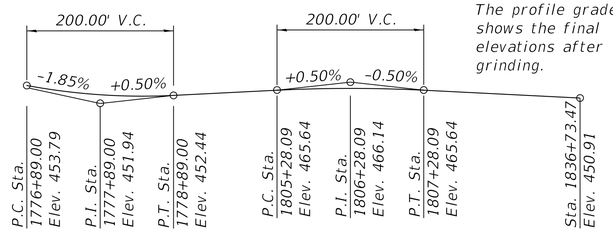
APPENDIX G
TSL

Benchmark:
BM2316-4: Cut "□" on Southwest corner of South wing wall at the West end of the Old Chain of Rocks Bridge over the Mississippi River (Missouri). Elev. 439.761'
BM2316-5: RR spike in power pole at the Northwest corner of Riverview Drive and Coal Bank Road (Missouri). Elev. 430.055'
Existing Structure: SN 060-0035 Steel girder and concrete slab superstructure bridge on piers. Approximately in line with Westbound structure. Approximately 5411.0' long by 62'-9" wide. Constructed in 1966. To be removed after proposed EB Structure No. 060-0350 is complete.
Traffic Control: none
No Salvage

Notes:
All Elevations are given in NAVD 1988 Datum unless noted.
NAVD 1988 = NGVD 1929 - 0.20'.
EWSE = Estimated Water Surface Elevation.
HWE = High Water Elevation.
For ground elevations see Sheet 8.
⊕ Denotes soil boring.
Proposed lighting unit: 50 ft. aluminum pole, 15" bolt circle diameter, mounted on bridge parapet wall.
Lighting unit is subject to refinement during the design phase.
Estimated Top of Rock Elevations shown at the substructures will be subject to refinement during final design.
Ripap shall be capped with 2" stone for drivability. Location to be determined during final design.



LOCATION SKETCH



The profile grade shows the final elevations after grinding.

PROFILE GRADE - I-270 EB

Bridge Omission from Sta. 1779+84.86 to 1834+39.33

I-270 OVER THE MISSISSIPPI RIVER
PUBLIC WATER
F.A.I. Rte. 270 - SEC. 60B-1
MADISON (IL) AND ST. LOUIS (MO) COUNTIES
STATION 2807+06.64
STRUCTURE NO. 060-0351 (WB)

Notes:
All Elevations are given in NAVD 1988 Datum unless noted.
EWSE = Estimated Water Surface Elevation.
HWE = High Water Elevation.
For ground elevations see Sheet 7.
Denotes soil boring.

Notes (continued):
Proposed lighting unit: 50 ft. aluminum pole, 15" bolt circle diameter, mounted on bridge parapet wall.
Lighting unit is subject to refinement during the design phase.
Estimated Top of Rock Elevations shown at the substructures will be subject to refinement during final design.

(1) DS-11 Scupper, typ., U.N.O.

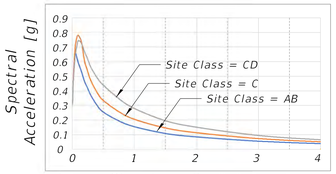
(2) 3 spaces at 15'-0" centers

SEISMIC DATA

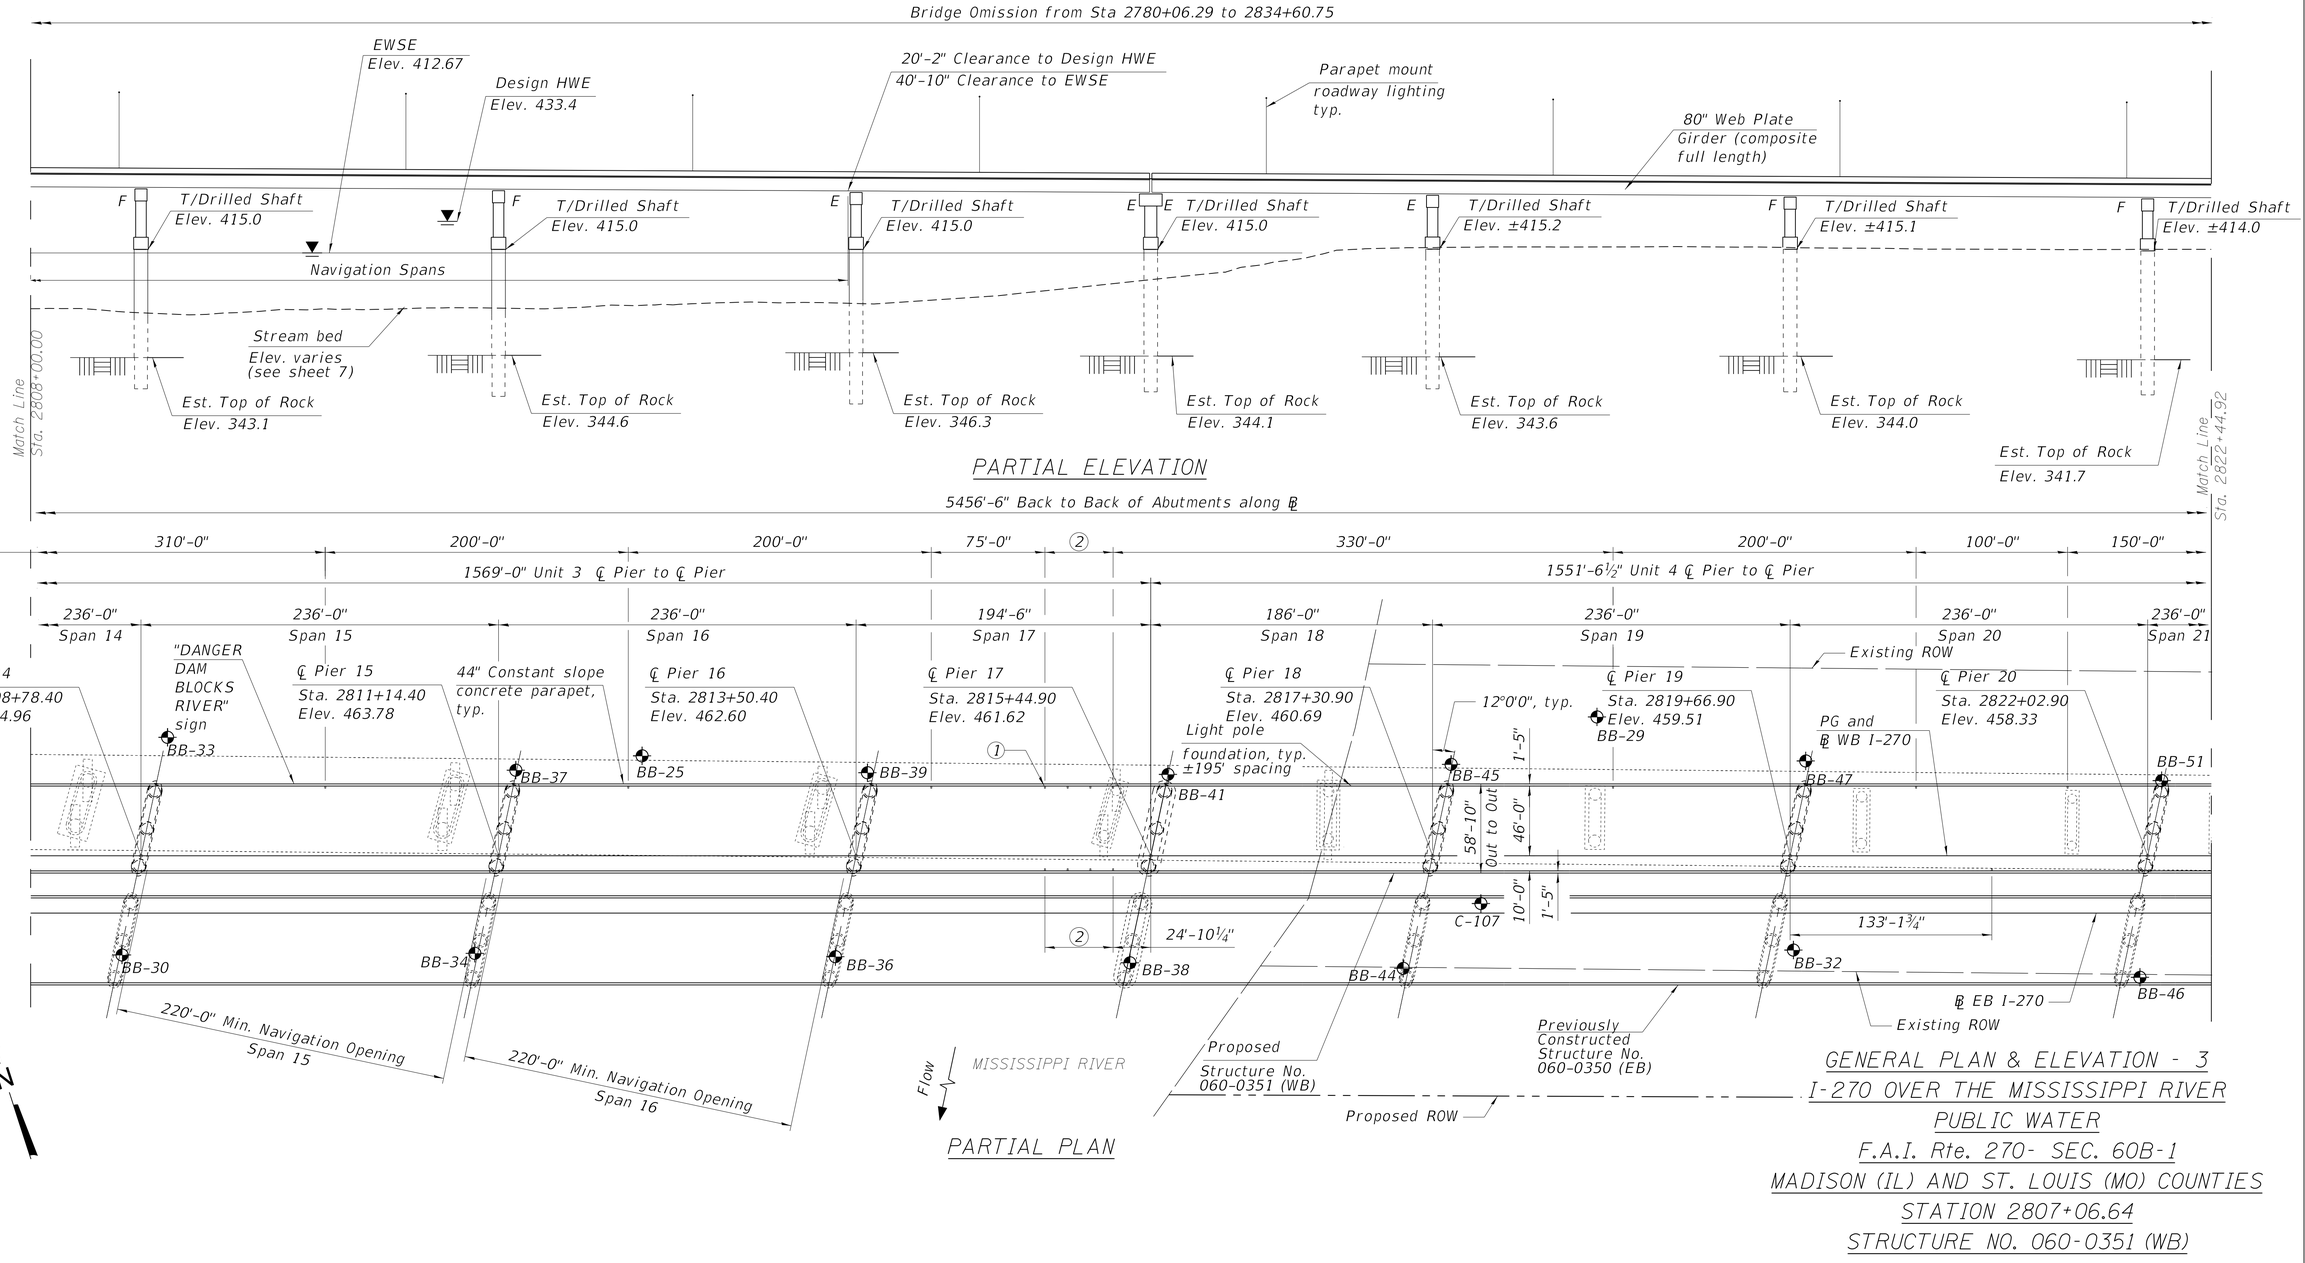
Seismic Performance Zone (SPZ) = 2
Operational Classification: Critical

Seismic Data based on Site-Specific Data			
	West Abut. Piers 1-3	Piers 4-16	Piers 17-25 East Abut.
Site Class	C	AB	CD
Design Spectral Acceleration at 1.0 sec, S_{D1} [g]	0.204	0.153	0.279
Design Spectral Acceleration at 0.2 sec, S_{DS} [g]	0.608	0.465	0.668

SITE - SPECIFIC UNIFORM HAZARD SPECTRA



Bridge Omission from Sta 2780+06.29 to 2834+60.75



PARTIAL ELEVATION

5456'-6" Back to Back of Abutments along ℄

Scupper spacing	310'-0"	200'-0"	200'-0"	75'-0"	(2)	330'-0"	200'-0"	100'-0"	150'-0"

Important Information about Your

Geotechnical Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

Geotechnical Services Are Performed for Specific Purposes, Persons, and Projects

Geotechnical engineers structure their services to meet the specific needs of their clients. A geotechnical engineering study conducted for a civil engineer may not fulfill the needs of a construction contractor or even another civil engineer. Because each geotechnical engineering study is unique, each geotechnical engineering report is unique, prepared *solely* for the client. No one except you should rely on your geotechnical engineering report without first conferring with the geotechnical engineer who prepared it. *And no one — not even you* — should apply the report for any purpose or project except the one originally contemplated.

Read the Full Report

Serious problems have occurred because those relying on a geotechnical engineering report did not read it all. Do not rely on an executive summary. Do not read selected elements only.

A Geotechnical Engineering Report Is Based on A Unique Set of Project-Specific Factors

Geotechnical engineers consider a number of unique, project-specific factors when establishing the scope of a study. Typical factors include: the client's goals, objectives, and risk management preferences; the general nature of the structure involved, its size, and configuration; the location of the structure on the site; and other planned or existing site improvements, such as access roads, parking lots, and underground utilities. Unless the geotechnical engineer who conducted the study specifically indicates otherwise, do not rely on a geotechnical engineering report that was:

- not prepared for you,
- not prepared for your project,
- not prepared for the specific site explored, or
- completed before important project changes were made.

Typical changes that can erode the reliability of an existing geotechnical engineering report include those that affect:

- the function of the proposed structure, as when it's changed from a parking garage to an office building, or from a light industrial plant to a refrigerated warehouse,
- elevation, configuration, location, orientation, or weight of the proposed structure,
- composition of the design team, or
- project ownership.

As a general rule, *always* inform your geotechnical engineer of project changes—even minor ones—and request an assessment of their impact. *Geotechnical engineers cannot accept responsibility or liability for problems that occur because their reports do not consider developments of which they were not informed.*

Subsurface Conditions Can Change

A geotechnical engineering report is based on conditions that existed at the time the study was performed. *Do not rely on a geotechnical engineering report* whose adequacy may have been affected by: the passage of time; by man-made events, such as construction on or adjacent to the site; or by natural events, such as floods, earthquakes, or groundwater fluctuations. *Always* contact the geotechnical engineer before applying the report to determine if it is still reliable. A minor amount of additional testing or analysis could prevent major problems.

Most Geotechnical Findings Are Professional Opinions

Site exploration identifies subsurface conditions only at those points where subsurface tests are conducted or samples are taken. Geotechnical engineers review field and laboratory data and then apply their professional judgment to render an opinion about subsurface conditions throughout the site. Actual subsurface conditions may differ—sometimes significantly—from those indicated in your report. Retaining the geotechnical engineer who developed your report to provide construction observation is the most effective method of managing the risks associated with unanticipated conditions.

A Report's Recommendations Are *Not* Final

Do not overrely on the construction recommendations included in your report. *Those recommendations are not final,* because geotechnical engineers develop them principally from judgment and opinion. Geotechnical engineers can finalize their recommendations only by observing actual

subsurface conditions revealed during construction. *The geotechnical engineer who developed your report cannot assume responsibility or liability for the report's recommendations if that engineer does not perform construction observation.*

A Geotechnical Engineering Report Is Subject to Misinterpretation

Other design team members' misinterpretation of geotechnical engineering reports has resulted in costly problems. Lower that risk by having your geotechnical engineer confer with appropriate members of the design team after submitting the report. Also retain your geotechnical engineer to review pertinent elements of the design team's plans and specifications. Contractors can also misinterpret a geotechnical engineering report. Reduce that risk by having your geotechnical engineer participate in prebid and preconstruction conferences, and by providing construction observation.

Do Not Redraw the Engineer's Logs

Geotechnical engineers prepare final boring and testing logs based upon their interpretation of field logs and laboratory data. To prevent errors or omissions, the logs included in a geotechnical engineering report should *never* be redrawn for inclusion in architectural or other design drawings. Only photographic or electronic reproduction is acceptable, *but recognize that separating logs from the report can elevate risk.*

Give Contractors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can make contractors liable for unanticipated subsurface conditions by limiting what they provide for bid preparation. To help prevent costly problems, give contractors the complete geotechnical engineering report, *but* preface it with a clearly written letter of transmittal. In that letter, advise contractors that the report was not prepared for purposes of bid development and that the report's accuracy is limited; encourage them to confer with the geotechnical engineer who prepared the report (a modest fee may be required) and/or to conduct additional study to obtain the specific types of information they need or prefer. A prebid conference can also be valuable. *Be sure contractors have sufficient time* to perform additional study. Only then might you be in a position to give contractors the best information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions.

Read Responsibility Provisions Closely

Some clients, design professionals, and contractors do not recognize that geotechnical engineering is far less exact than other engineering disciplines. This lack of understanding has created unrealistic expectations that have led to disappointments, claims, and disputes. To help reduce the risk of such outcomes, geotechnical engineers commonly include a variety of explanatory provisions in their reports. Sometimes labeled "limitations" many of these provisions indicate where geotechnical engineers' responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely.* Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The equipment, techniques, and personnel used to perform a *geoenvironmental* study differ significantly from those used to perform a *geotechnical* study. For that reason, a geotechnical engineering report does not usually relate any geoenvironmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. *Unanticipated environmental problems have led to numerous project failures.* If you have not yet obtained your own geoenvironmental information, ask your geotechnical consultant for risk management guidance. *Do not rely on an environmental report prepared for someone else.*

Obtain Professional Assistance To Deal with Mold

Diverse strategies can be applied during building design, construction, operation, and maintenance to prevent significant amounts of mold from growing on indoor surfaces. To be effective, all such strategies should be devised for the *express purpose* of mold prevention, integrated into a comprehensive plan, and executed with diligent oversight by a professional mold prevention consultant. Because just a small amount of water or moisture can lead to the development of severe mold infestations, a number of mold prevention strategies focus on keeping building surfaces dry. While groundwater, water infiltration, and similar issues may have been addressed as part of the geotechnical engineering study whose findings are conveyed in this report, the geotechnical engineer in charge of this project is not a mold prevention consultant; ***none of the services performed in connection with the geotechnical engineer's study were designed or conducted for the purpose of mold prevention. Proper implementation of the recommendations conveyed in this report will not of itself be sufficient to prevent mold from growing in or on the structure involved.***

Rely, on Your ASFE-Member Geotechncial Engineer for Additional Assistance

Membership in ASFE/The Best People on Earth exposes geotechnical engineers to a wide array of risk management techniques that can be of genuine benefit for everyone involved with a construction project. Confer with your ASFE-member geotechnical engineer for more information.
